This form of inheritance is called *simple* inheritance in R. See [setClass](#) for details. Inheritance can also be defined explicitly by a call to [setIs](#). The two versions have slightly different implications for coerce methods. Simple inheritance implies that inherited slots behave identically in the subclass and the superclass. Whenever two classes are related by simple inheritance, corresponding coerce methods are defined for both direct and replacement use of as. In the case of simple inheritance, these methods do the obvious computation: they extract or replace the slots in the object that correspond to those in the superclass definition.

The implicitly defined coerce methods may be overridden by a call to [setAs](#); note, however, that the implicit methods are defined for each subclass-superclass pair, so that you must override each of these explicitly, not rely on inheritance.

When inheritance is defined by a call to [setIs](#), the coerce methods are provided explicitly, not generated automatically. Inheritance will apply (to the from argument, as described in the section below). You could also supply methods via [setAs](#) for non-inherited relationships, and now these also can be inherited.

For further on the distinction between simple and explicit inheritance, see [setIs](#).

## How Functions 'as' and 'setAs' Work

The function as turns object into an object of class Class. In doing so, it applies a “coerce method”, using S4 classes and methods, but in a somewhat special way. Coerce methods are methods for the function coerce or, in the replacement case the function coerce<- . These functions have two arguments in method signatures, from and to, corresponding to the class of the object and the desired coerce class. These functions must not be called directly, but are used to store tables of methods for the use of as, directly and for replacements. In this section we will describe the direct case, but except where noted the replacement case works the same way, using coerce<- and the replace argument to [setAs](#), rather than coerce and the def argument.

Assuming the object is not already of the desired class, as first looks for a method in the table of methods for the function coerce for the signature c(from = class(object), to = Class), in the same way method selection would do its initial lookup. To be precise, this means the table of both direct and inherited methods, but inheritance is used specially in this case (see below).

If no method is found, as looks for one. First, if either Class or class(object) is a superclass of the other, the class definition will contain the information needed to construct a coerce method. In the usual case that the subclass contains the superclass (i.e., has all its slots), the method is constructed either by extracting or replacing the inherited slots. Non-simple extensions (the result of a call to [setIs](#)) will usually contain explicit methods, though possibly not for replacement.

If no subclass/superclass relationship provides a method, as looks for an inherited method, but applying, inheritance for the argument from only, not for the argument to (if you think about it, you'll probably agree that you wouldn't want the result to be from some class other than the Class specified). Thus, `selectMethod("coerce", sig, useInherited= c(from=TRUE, to= FALSE))` replicates the method selection used by as().

In nearly all cases the method found in this way will be cached in the table of coerce methods (the exception being subclass relationships with a test, which are legal but discouraged). So the detailed calculations should be done only on the first occurrence of a coerce from class(object) to Class.

Note that coerce is not a standard generic function. It is not intended to be called directly. To prevent accidentally caching an invalid inherited method, calls are routed to an equivalent call to as, and a warning is issued. Also, calls to [selectMethod](#) for this function may not represent the method that as will choose. You can only trust the result if the corresponding call to as has occurred previously in this session.

With this explanation as background, the function `setAs` does a fairly obvious computation: It constructs and sets a method for the function `coerce` with signature `c(from, to)`, using the `def` argument to define the body of the method. The function supplied as `def` can have one argument (interpreted as an object to be coerced) or two arguments (the `from` object and the `to` class). Either way, `setAs` constructs a function of two arguments, with the second defaulting to the name of the `to` class. The method will be called from `as` with the object as the `from` argument and no `to` argument, with the default for this argument being the name of the intended `to` class, so the method can use this information in messages.

The direct version of the `as` function also has a `strict=` argument that defaults to `TRUE`. Calls during the evaluation of methods for other functions will set this argument to `FALSE`. The distinction is relevant when the object being coerced is from a simple subclass of the `to` class; if `strict=FALSE` in this case, nothing need be done. For most user-written coerce methods, when the two classes have no subclass/superclass, the `strict=` argument is irrelevant.

The `replace` argument to `setAs` provides a method for `coerce<-`. As with all replacement methods, the last argument of the method must have the name `value` for the object on the right of the assignment. As with the `coerce` method, the first two arguments are `from, to`; there is no `strict=` option for the replace case.

The function `coerce` exists as a repository for such methods, to be selected as described above by the `as` function. Actually dispatching the methods using `standardGeneric` could produce incorrect inherited methods, by using inheritance on the `to` argument; as mentioned, this is not the logic used for `as`. To prevent selecting and caching invalid methods, calls to `coerce` are currently mapped into calls to `as`, with a warning message.

## Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, `as(x, "numeric")` uses the existing `as.numeric` function. These built-in methods can be listed by `showMethods("coerce")`.

## See Also

If you think of using `try(as(x, cl))`, consider `canCoerce(x, cl)` instead.

## Examples

```
using the definition of class "track" from \link{setClass}

setAs("track", "numeric", function(from) from@y)

t1 <- new("track", x=1:20, y=(1:20)^2)

as(t1, "numeric")

The next example shows:
1. A virtual class to define setAs for several classes at once.
```

```

2. as() using inherited information

setClass("ca", representation(a = "character", id = "numeric"))

setClass("cb", representation(b = "character", id = "numeric"))

setClass("id")
setIs("ca", "id")
setIs("cb", "id")

setAs("id", "numeric", function(from) from@id)

CA <- new("ca", a = "A", id = 1)
CB <- new("cb", b = "B", id = 2)

setAs("cb", "ca", function(from, to) new(to, a=from@b, id = from@id))

as(CB, "numeric")

```

**BasicClasses***Classes Corresponding to Basic Data Types***Description**

Formal classes exist corresponding to the basic R object types, allowing these types to be used in method signatures, as slots in class definitions, and to be extended by new classes.

**Usage**

```

The following are all basic vector classes.
They can appear as class names in method signatures,
in calls to as(), is(), and new().
"character"
"complex"
"double"
"expression"
"integer"
"list"
"logical"
"numeric"
"single"
"raw"

the class
"vector"
is a virtual class, extended by all the above

the class
"S4"
is an object type for S4 objects that do not extend

```

```

any of the basic vector classes. It is a virtual class.

The following are additional basic classes
"NULL" # NULL objects
"function" # function objects, including primitives
"externalptr" # raw external pointers for use in C code

"ANY" # virtual classes used by the methods package itself
"VIRTUAL"
"missing"

"namedList" # the alternative to "list" that preserves
 # the names attribute

```

### Objects from the Classes

If a class is not virtual (see section in [Classes](#)), objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted class name, and the remaining arguments if any are objects to be interpreted as vectors of this class. Multiple arguments will be concatenated.

The class "expression" is slightly odd, in that the `...` arguments will *not* be evaluated; therefore, don't enclose them in a call to `quote()`.

Note that class "list" is a pure vector. Although lists with names go back to the earliest versions of S, they are an extension of the vector concept in that they have an attribute (which can now be a slot) and which is either NULL or a character vector of the same length as the vector. If you want to guarantee that list names are preserved, use class "namedList", rather than "list". Objects from this class must have a `names` attribute, corresponding to slot "names", of type "character". Internally, R treats names for lists specially, which makes it impractical to have the corresponding slot in class "namedList" be a union of character names and NULL.

### Classes and Types

The basic classes include classes for the basic R types. Note that objects of these types will not usually be S4 objects (`isS4` will return FALSE), although objects from classes that contain the basic class will be S4 objects, still with the same type. The type as returned by `typeof` will sometimes differ from the class, either just from a choice of terminology (type "symbol" and class "name", for example) or because there is not a one-to-one correspondence between class and type (most of the classes that inherit from class "language" have type "language", for example).

### Extends

The vector classes extend "vector", directly.

### Methods

**coerce** Methods are defined to coerce arbitrary objects to the vector classes, by calling the corresponding basic function, for example, `as(x, "numeric")` calls `as.numeric(x)`.

---

**callGeneric**

*Call the Current Generic Function from a Method*

---

**Description**

A call to `callGeneric` can only appear inside a method definition. It then results in a call to the current generic function. The value of that call is the value of `callGeneric`. While it can be called from any method, it is useful and typically used in methods for group generic functions.

**Usage**

```
callGeneric(...)
```

**Arguments**

...

Optionally, the arguments to the function in its next call.

If no arguments are included in the call to `callGeneric`, the effect is to call the function with the current arguments. See the detailed description for what this really means.

**Details**

The name and package of the current generic function is stored in the environment of the method definition object. This name is looked up and the corresponding function called.

The statement that passing no arguments to `callGeneric` causes the generic function to be called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say `x`, that appears in the original call, there is a corresponding argument in the generated call equivalent to `x = x`. In effect, this means that the generic function sees the same actual arguments, but arguments are evaluated only once.

Using `callGeneric` with no arguments is prone to creating infinite recursion, unless one of the arguments in the signature has been modified in the current method so that a different method is selected.

**Value**

The value returned by the new call.

## Examples

```
the method for group generic function Ops
for signature(e1="structure", e2="vector")
function (e1, e2)
{
 value <- callGeneric(e1@.Data, e2)
 if (length(value) == length(e1)) {
 e1@.Data <- value
 e1
 }
 else value
}

For more examples
Not run:
showMethods("Ops", includeDefs = TRUE)

End(Not run)
```

callNextMethod

*Call an Inherited Method*

## Description

A call to `callNextMethod` can only appear inside a method definition. It then results in a call to the first inherited method after the current method, with the arguments to the current method passed down to the next method. The value of that method call is the value of `callNextMethod`.

## Usage

```
callNextMethod(...)
```

## Arguments

...      Optionally, the arguments to the function in its next call (but note that the dispatch is as in the detailed description below; the arguments have no effect on selecting the next method.)

If no arguments are included in the call to `callNextMethod`, the effect is to call the method with the current arguments. See the detailed description for what this really means.

Calling with no arguments is often the natural way to use `callNextMethod`; see the examples.

## Details

The ‘next’ method (i.e., the first inherited method) is defined to be that method which *would* have been called if the current method did not exist. This is more-or-less literally what happens: The current method (to be precise, the method with signature given by the `defined` slot of the method from which `callNextMethod` is called) is deleted from a copy of the methods for the current generic, and `selectMethod` is called to find the next method (the result is cached in a special object, so the search only typically happens once per session per combination of argument classes).

Note that the preceding definition means that the next method is defined uniquely when `setMethod` inserts the method containing the `callNextMethod` call, given the definitions of the classes in the signature. The choice does not depend on the path that gets us to that method (for example, through inheritance or from another `callNextMethod` call). This definition was not enforced in versions of R prior to 2.3.0, where the method was selected based on the target signature, and so could vary depending on the actual arguments.

It is also legal, and often useful, for the method called by `callNextMethod` to itself have a call to `callNextMethod`. This generally works as you would expect, but for completeness be aware that it is possible to have ambiguous inheritance in the S structure, in the sense that the same two classes can appear as superclasses *in the opposite order* in two other class definitions. In this case the effect of a nested instance of `callNextMethod` is not well defined. Such inconsistent class hierarchies are both rare and nearly always the result of bad design, but they are possible, and currently undetected.

The statement that the method is called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say `x`, that appears in the original call, there is a corresponding argument in the next method call equivalent to `x = x`. In effect, this means that the next method sees the same actual arguments, but arguments are evaluated only once.

### Value

The value returned by the selected method.

### See Also

[callGeneric](#) to call the generic function with the current dispatch rules (typically for a group generic function); [Methods](#) for the general behavior of method dispatch.

### Examples

```
some class definitions with simple inheritance
setClass("B0", representation(b0 = "numeric"))

setClass("B1", representation(b1 = "character"), contains = "B0")

setClass("B2", representation(b2 = "logical"), contains = "B1")

and a rather silly function to illustrate callNextMethod

f <- function(x) class(x)

setMethod("f", "B0", function(x) c(x@b0^2, callNextMethod()))
setMethod("f", "B1", function(x) c(paste(x@b1, ":"), callNextMethod()))
setMethod("f", "B2", function(x) c(x@b2, callNextMethod()))

b1 <- new("B1", b0 = 2, b1 = "Testing")

b2 <- new("B2", b2 = FALSE, b1 = "More testing", b0 = 10)
```

```
f(b2)
stopifnot(identical(f(b2), c(b2@b2, paste(b2@b1, ":"), b2@b0^2, "B2")))

f(b1)

a sneakier method: the *changed* x is used:
setMethod("f", "B2",
 function(x) {x@b0 <- 111; c(x@b2, callNextMethod())})
f(b2)
stopifnot(identical(f(b2), c(b2@b2, paste(b2@b1, ":"), 111^2, "B2")))
```

**canCoerce***Can an Object be Coerced to a Certain S4 Class?***Description**

Test if an object can be coerced to a given S4 class. Maybe useful inside `if()` to ensure that calling `as(object, Class)` will find a method.

**Usage**

```
canCoerce(object, Class)
```

**Arguments**

|                     |                                               |
|---------------------|-----------------------------------------------|
| <code>object</code> | any R object, typically of a formal S4 class. |
| <code>Class</code>  | an S4 class (see <a href="#">isClass</a> ).   |

**Value**

a scalar logical, TRUE if there is a coerce method (as defined by [setAs](#), e.g.) for the signature (`from = class(object)`, `to = Class`).

**See Also**

[as](#), [setAs](#), [selectMethod](#), [setClass](#),

**Examples**

```
m <- matrix(pi, 2,3)
canCoerce(m, "numeric") # TRUE
canCoerce(m, "array") # TRUE
```

**cbind2***Combine two Objects by Columns or Rows***Description**

Combine two matrix-like R objects by columns (`cbind2`) or rows (`rbind2`). These are (S4) generic functions with default methods.

**Usage**

```
cbind2(x, y, ...)
rbind2(x, y, ...)
```

**Arguments**

- `x` any R object, typically matrix-like.
- `y` any R object, typically similar to `x`, or missing completely.
- `...` optional arguments for methods.

**Details**

The main use of `cbind2` (`rbind2`) is to be called by `cbind()` (`rbind()`) if these are activated. This allows `cbind` (`rbind`) to work for formally classed (aka ‘S4’) objects by providing S4 methods for these objects. Currently, a call  
`methods:::bind_activation(TRUE)`  
is needed to install a `cbind2`-calling version of `cbind` (into the `base` namespace) and the same for `rbind`.  
`methods:::bind_activation(FALSE)` reverts to the previous internal version of `cbind` which does not build on `cbind2`, see the examples.

**Value**

A matrix (or matrix like object) combining the columns (or rows) of `x` and `y`.

**Methods**

- `signature(x = "ANY", y = "ANY")` the default method using R’s internal code.
- `signature(x = "ANY", y = "missing")` the default method for one argument using R’s internal code.

**See Also**

`cbind`, `rbind`; further, `cBind`, `rBind` in the **Matrix** package.

**Examples**

```
cbind2(1:3, 4)
m <- matrix(3:8, 2, 3, dimnames=list(c("a", "b"), LETTERS[1:3]))
cbind2(1:2, m) # keeps dimnames from m

Note: Use the following activation if you want cbind() to work
----- on S4 objects -- be careful otherwise!
```

```

methods:::bind_activation(on = TRUE)
trace("cbind2")
cbind(a=1:3)# no call to cbind2()
cbind(a=1:3, four=4, 7:9)# calling cbind2() twice
untrace("cbind2")

cbind(m, a=1, b=3)

turn off the special cbind() :
methods:::bind_activation(FALSE)

```

**Classes***Class Definitions***Description**

Class definitions are objects that contain the formal definition of a class of R objects, usually referred to as an S4 class, to distinguish them from the informal S3 classes. This document gives an overview of S4 classes; for details of the class representation objects, see help for the class [classRepresentation](#).

**Metadata Information**

When a class is defined, an object is stored that contains the information about that class. The object, known as the *metadata* defining the class, is not stored under the name of the class (to allow programmers to write generating functions of that name), but under a specially constructed name. To examine the class definition, call [getClass](#). The information in the metadata object includes:

**Slots:** The data contained in an object from an S4 class is defined by the *slots* in the class definition.

Each slot in an object is a component of the object; like components (that is, elements) of a list, these may be extracted and set, using the function [slot\(\)](#) or more often the operator "`@`". However, they differ from list components in important ways. First, slots can only be referred to by name, not by position, and there is no partial matching of names as with list elements.

All the objects from a particular class have the same set of slot names; specifically, the slot names that are contained in the class definition. Each slot in each object always is an object of the class specified for this slot in the definition of the current class. The word "is" corresponds to the R function of the same name ([is](#)), meaning that the class of the object in the slot must be the same as the class specified in the definition, or some class that extends the one in the definition (a *subclass*).

A special slot name, `.Data`, stands for the 'data part' of the object. An object from a class with a data part is defined by specifying that the class contains one of the R object types or one of the special pseudo-classes, `matrix` or `array`, usually because the definition of the class, or of one of its superclasses, has included the type or pseudo-class in its `contains` argument. A second special slot name, `.xData`, is used to enable inheritance from abnormal types such as "environment". See the section on inheriting from non-S4 classes for details on the representation and for the behavior of S3 methods with objects from these classes.

Some slot names correspond to attributes used in old-style S3 objects and in R objects without an explicit class, for example, the `names` attribute. If you define a class for which that attribute

will be set, such as a subclass of named vectors, you should include "names" as a slot. See the definition of class "namedList" for an example. Using the `names()` assignment to set such names will generate a warning if there is no names slot and an error if the object in question is not a vector type. A slot called "names" can be used anywhere, but only if it is assigned as a slot, not via the default `names()` assignment.

**Superclasses:** The definition of a class includes the *superclasses* —the classes that this class extends. A class `Fancy`, say, extends a class `Simple` if an object from the `Fancy` class has all the capabilities of the `Simple` class (and probably some more as well). In particular, and very usefully, any method defined to work for a `Simple` object can be applied to a `Fancy` object as well.

This relationship is expressed equivalently by saying that `Simple` is a superclass of `Fancy`, or that `Fancy` is a subclass of `Simple`.

The direct superclasses of a class are those superclasses explicitly defined. Direct superclasses can be defined in three ways. Most commonly, the superclasses are listed in the `contains=` argument in the call to `setClass` that creates the subclass. In this case the subclass will contain all the slots of the superclass, and the relation between the class is called *simple*, as it in fact is. Superclasses can also be defined explicitly by a call to `setIs`; in this case, the relation requires methods to be specified to go from subclass to superclass. Thirdly, a class union is a superclass of all the members of the union. In this case too the relation is simple, but notice that the relation is defined when the superclass is created, not when the subclass is created as with the `contains=` mechanism.

The definition of a superclass will also potentially contain its own direct superclasses. These are considered (and shown) as superclasses at distance 2 from the original class; their direct superclasses are at distance 3, and so on. All these are legitimate superclasses for purposes such as method selection.

When superclasses are defined by including the names of superclasses in the `contains=` argument to `setClass`, an object from the class will have all the slots defined for its own class *and* all the slots defined for all its superclasses as well.

The information about the relation between a class and a particular superclass is encoded as an object of class `SClassExtension`. A list of such objects for the superclasses (and sometimes for the subclasses) is included in the metadata object defining the class. If you need to compute with these objects (for example, to compare the distances), call the function `extends` with argument `fullInfo=TRUE`.

**Prototype:** The objects from a class created by a call to `new` are defined by the *prototype* object for the class and by additional arguments in the call to `new`, which are passed to a method for that class for the function `initialize`.

Each class representation object contains a prototype object for the class (although for a virtual class the prototype may be `NULL`). The prototype object must have values for all the slots of the class. By default, these are the prototypes of the corresponding slot classes. However, the definition of the class can specify any valid object for any of the slots.

## Virtual classes; Basic classes

Classes exist for which no actual objects can be created by a call to `new`, the *virtual* classes, in fact a very important programming tool. They are used to group together ordinary classes that want to share some programming behavior, without necessarily restricting how the behavior is implemented. Virtual class definitions may if you want include slots (to provide some common behavior without fully defining the object—see the class `traceable` for an example).

A simple and useful form of virtual class is the *class union*, a virtual class that is defined in a call to `setClassUnion` by listing one or more of subclasses (classes that extend the class union). Class unions can include as subclasses basic object types (whose definition is otherwise sealed).

There are a number of ‘basic’ classes, corresponding to the ordinary kinds of data occurring in R. For example, “numeric” is a class corresponding to numeric vectors. The other vector basic classes are “logical”, “integer”, “complex”, “character”, “raw”, “list” and “expression”. The prototypes for the vector classes are vectors of length 0 of the corresponding type. Notice that basic classes are unusual in that the prototype object is from the class itself.

In addition to the vector classes there are also basic classes corresponding to objects in the language, such as “function” and “call”. These classes are subclasses of the virtual class “language”. Finally, there are object types and corresponding basic classes for “abnormal” objects, such as “environment” and “externalptr”. These objects do not follow the functional behavior of the language; in particular, they are not copied and so cannot have attributes or slots defined locally.

All these classes can be used as slots or as superclasses for any other class definitions, although they do not themselves come with an explicit class. For the abnormal object types, a special mechanism is used to enable inheritance as described below.

### Inheriting from non-S4 Classes

A class definition can extend classes other than regular S4 classes, usually by specifying them in the `contains=` argument to `setClass`. Three groups of such classes behave distinctly:

1. S3 classes, which must have been registered by a previous call to `setOldClass` (you can check that this has been done by calling `getClass`, which should return a class that extends `oldClass`);
2. One of the R object types, typically a vector type, which then defines the type of the S4 objects, but also a type such as `environment` that can not be used directly as a type for an S4 object. See below.
3. One of the pseudo-classes `matrix` and `array`, implying objects with arbitrary vector types plus the `dim` and `dimnames` attributes.

This section describes the approach to combining S4 computations with older S3 computations by using such classes as superclasses. The design goal is to allow the S4 class to inherit S3 methods and default computations in as consistent a form as possible.

As part of a general effort to make the S4 and S3 code in R more consistent, when objects from an S4 class are used as the first argument to a non-default S3 method, either for an S3 generic function (one that calls `UseMethod`) or for one of the primitive functions that dispatches S3 methods, an effort is made to provide a valid object for that method. In particular, if the S4 class extends an S3 class or `matrix` or `array`, and there is an S3 method matching one of these classes, the S4 object will be coerced to a valid S3 object, to the extent that is possible given that there is no formal definition of an S3 class.

For example, suppose “myFrame” is an S4 class that includes the S3 class “`data.frame`” in the `contains=` argument to `setClass`. If an object from this S4 class is passed to a function, say `as.matrix`, that has an S3 method for “`data.frame`”, the internal code for `UseMethod` will convert the object to a data frame; in particular, to an S3 object whose class attribute will be the vector corresponding to the S3 class (possibly containing multiple class names). Similarly for an S4 object inheriting from “`matrix`” or “`array`”, the S4 object will be converted to a valid S3 matrix or array.

Note that the conversion is *not* applied when an S4 object is passed to the default S3 method. Some S3 generics attempt to deal with general objects, including S4 objects. Also, no transformation is applied to S4 objects that do not correspond to a selected S3 method; in particular, to objects from a class that does not contain either an S3 class or one of the basic types. See `asS4` for the transformation details.

In addition to explicit S3 generic functions, S3 methods are defined for a variety of operators and functions implemented as primitives. These methods are dispatched by some internal C code that

operates partly through the same code as real S3 generic functions and partly via special considerations (for example, both arguments to a binary operator are examined when looking for methods). The same mechanism for adapting S4 objects to S3 methods has been applied to these computations as well, with a few exceptions such as generating an error if an S4 object that does not extend an appropriate S3 class or type is passed to a binary operator.

The remainder of this section discusses the mechanisms for inheriting from basic object types. See [matrix](#) or [array](#) for inheriting from the matrix and array pseudo-classes, or from time-series. For the corresponding details for inheritance from S3 classes, see [setOldClass](#).

An object from a class that directly and simply contains one of the basic object types in R, has implicitly a corresponding .Data slot of that type, allowing computations to extract or replace the data part while leaving other slots unchanged. If the type is one that can accept attributes and is duplicated normally, the inheritance also determines the type of the object; if the class definition has a .Data slot corresponding to a normal type, the class of the slot determines the type of the object (that is, the value of `typeof(x)`). For such classes, .Data is a pseudo-slot; that is, extracting or setting it modifies the non-slot data in the object. The functions [getDataPart](#) and [setDataPart](#) are a cleaner, but essentially equivalent way to deal with the data part.

Extending a basic type this way allows objects to use old-style code for the corresponding type as well as S4 methods. Any basic type can be used for .Data, but a few types are treated differently because they do not behave like ordinary objects; for example, "NULL", environments, and external pointers. Classes extend these types by having a slot, .xData, itself inherited from an internally defined S4 class. This slot actually contains an object of the inherited type, to protect computations from the reference semantics of the type. Coercing to the nonstandard object type then requires an actual computation, rather than the "simple" inclusion for other types and classes. The intent is that programmers will not need to take account of the mechanism, but one implication is that you should *not* explicitly use the type of an S4 object to detect inheritance from an arbitrary object type. Use [is](#) and similar functions instead.

## Description

Given a vector of class names or a list of class definitions, the function returns an adjacency matrix of the superclasses of these classes; that is, a matrix with class names as the row and column names and with element  $[i, j]$  being 1 if the class in column  $j$  is a direct superclass of the class in row  $i$ , and 0 otherwise.

The matrix has the information implied by the `contains` slot of the class definitions, but in a form that is often more convenient for further analysis; for example, an adjacency matrix is used in packages and other software to construct graph representations of relationships.

## Usage

```
classesToAM(classes, includeSubclasses = FALSE,
 abbreviate = 2)
```

## Arguments

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>classes</code>           | Either a character vector of class names or a list, whose elements can be either class names or class definitions. The list is convenient, for example, to include the package slot for the class name. See the examples.                                                                                                                                                                                                                                    |
| <code>includeSubclasses</code> | A logical flag; if <code>TRUE</code> , then the matrix will include all the known subclasses of the specified classes as well as the superclasses. The argument can also be a logical vector of the same length as <code>classes</code> , to include subclasses for some but not all the classes.                                                                                                                                                            |
| <code>abbreviate</code>        | Control of the abbreviation of the row and/or column labels of the matrix returned: values 0, 1, 2, or 3 abbreviate neither, rows, columns or both. The default, 2, is useful for printing the matrix, since class names tend to be more than one character long, making for spread-out printing. Values of 0 or 3 would be appropriate for making a graph (3 avoids the tendency of some graph plotting software to produce labels in minuscule font size). |

## Details

For each of the classes, the calculation gets all the superclass names from the class definition, and finds the edges in those classes' definitions; that is, all the superclasses at distance 1. The corresponding elements of the adjacency matrix are set to 1.

The adjacency matrices for the individual class definitions are merged. Note two possible kinds of inconsistency, neither of which should cause problems except possibly with identically named classes from different packages. Edges are computed from each superclass definition, so that information overrides a possible inference from extension elements with distance > 1 (and it should). When matrices from successive classes in the argument are merged, the computations do not currently check for inconsistencies—this is the area where possible multiple classes with the same name could cause confusion. A later revision may include consistency checks.

## Value

As described, a matrix with entries 0 or 1, non-zero values indicating that the class corresponding to the column is a direct superclass of the class corresponding to the row. The row and column names are the class names (without package slot).

1000 *className*

## Examples

```
the super- and subclasses of "standardGeneric"
and "derivedDefaultMethod"
am <- classesToAM(list(class(show), class(getMethod(show))), TRUE)
am

Not run:
the following function depends on the Bioconductor package Rgraphviz
plotInheritance <- function(classes, subclasses = FALSE, ...) {
 if(!require("Rgraphviz", quietly=TRUE))
 stop("Only implemented if Rgraphviz is available")
 mm <- classesToAM(classes, subclasses)
 classes <- rownames(mm); rownames(mm) <- colnames(mm)
 graph <- new("graphAM", mm, "directed", ...)
 plot(graph)
 cat("Key:\n", paste(abbreviate(classes), " = ", classes, ", ",
 sep = ""), sep = "", fill = TRUE)
 invisible(graph)
}

The plot of the class inheritance of the package "graph"
require(graph)
plotInheritance(getClass("package:graph"))

End(Not run)
```

---

*className*

*Class names including the corresponding package*

---

## Description

The function `className()` generates a valid references to a class, including the name of the package containing the class definition. The object returned, from class "`className`", is the unambiguous way to refer to a class, for example when calling [setMethod](#), just in case multiple definitions of the class exist.

Function "`multipleClasses`" returns information about multiple definitions of classes with the same name from different packages.

## Usage

```
className(class, package)

multipleClasses(details = FALSE)
```

### Arguments

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>class</code> , <code>package</code> | The character string name of a class and, optionally, of the package to which it belongs. If argument <code>package</code> is missing and the <code>class</code> argument has a <code>package</code> slot, that is used (in particular, passing in an object from class "className" returns itself in this case, but changes the package slot if the second argument is supplied).<br>If there is no package argument or slot, a definition for the class must exist and will be used to define the package. If there are multiple definitions, one will be chosen and a warning printed giving the other possibilities. |
| <code>details</code>                      | If <code>FALSE</code> , the default, <code>multipleClasses()</code> returns a character vector of those classes currently known with multiple definitions.<br>If <code>TRUE</code> , a named list of those class definitions is returned. Each element of the list is itself a list of the corresponding class definitions, with the package names as the names of the list. Note that identical class definitions will not be considered "multiple" definitions (see the discussion of the details below).                                                                                                              |

### Details

The table of class definitions used internally can maintain multiple definitions for classes with the same name but coming from different packages. If identical class definitions are encountered, only one class definition is kept; this occurs most often with S3 classes that have been specified in calls to `setOldClass`. For true classes, multiple class definitions are unavoidable in general if two packages happen to have used the same name, independently.

Overriding a class definition in another package with the same name deliberately is usually a bad idea. Although R attempts to keep and use the two definitions (as of version 2.14.0), ambiguities are always possible. It is more sensible to define a new class that extends an existing class but has a different name.

### Value

A call to `className()` returns an object from class "className".

A call to `multipleClasses()` returns either a character vector or a named list of class definitions. In either case, testing the length of the returned value for being greater than 0 is a check for the existence of multiply defined classes.

### Objects from the Class

The class "className" extends "character" and has a slot "package", also of class "character".

### Examples

```
Not run:
className("vector") # will be found, from package "methods"
className("vector", "magic") # OK, even though the class doesn't exist

className("An unknown class") # Will cause an error

End(Not run)
```

---

classRepresentation-class  
*Class Objects*

---

## Description

These are the objects that hold the definition of classes of objects. They are constructed and stored as meta-data by calls to the function [setClass](#). Don't manipulate them directly, except perhaps to look at individual slots.

## Details

Class definitions are stored as metadata in various packages. Additional metadata supplies information on inheritance (the result of calls to [setIs](#)). Inheritance information implied by the class definition itself (because the class contains one or more other classes) is also constructed automatically.

When a class is to be used in an R session, this information is assembled to complete the class definition. The completion is a second object of class "classRepresentation", cached for the session or until something happens to change the information. A call to [getClass](#) returns the completed definition of a class; a call to [getClassDef](#) returns the stored definition (uncompleted).

In particular, completion fills in the upward- and downward-pointing inheritance information for the class, in slots `contains` and `subclasses` respectively. It's in principle important to note that this information can depend on which packages are installed, since these may define additional subclasses or superclasses.

## Slots

**slots:** A named list of the slots in this class; the elements of the list are the classes to which the slots must belong (or extend), and the names of the list gives the corresponding slot names.

**contains:** A named list of the classes this class 'contains'; the elements of the list are objects of [SClassExtension](#). The list may be only the direct extensions or all the currently known extensions (see the details).

**virtual:** Logical flag, set to TRUE if this is a virtual class.

**prototype:** The object that represents the standard prototype for this class; i.e., the data and slots returned by a call to [new](#) for this class with no special arguments. Don't mess with the prototype object directly.

**validity:** Optionally, a function to be used to test the validity of objects from this class. See [validObject](#).

**access:** Access control information. Not currently used.

**className:** The character string name of the class.

**package:** The character string name of the package to which the class belongs. Nearly always the package on which the metadata for the class is stored, but in operations such as constructing inheritance information, the internal package name rules.

**subclasses:** A named list of the classes known to extend this class'; the elements of the list are objects of class [SClassExtension](#). The list is currently only filled in when completing the class definition (see the details).

**versionKey:** Object of class "externalptr"; eventually will perhaps hold some versioning information, but not currently used.

**sealed:** Object of class "logical"; is this class sealed? If so, no modifications are allowed.

## See Also

See function `setClass` to supply the information in the class definition. See [Classes](#) for a more basic discussion of class information.

## Description

Special documentation can be supplied to describe the classes and methods that are created by the software in the `methods` package. Techniques to access this documentation and to create it in R help files are described here.

### Getting documentation on classes and methods

You can ask for on-line help for class definitions, for specific methods for a generic function, and for general discussion of methods for a generic function. These requests use the `?` operator (see [help](#) for a general description of the operator). Of course, you are at the mercy of the implementer as to whether there *is* any documentation on the corresponding topics.

Documentation on a class uses the argument `class` on the left of the `?`, and the name of the class on the right; for example,

```
class ? genericFunction
```

to ask for documentation on the class "genericFunction".

When you want documentation for the methods defined for a particular function, you can ask either for a general discussion of the methods or for documentation of a particular method (that is, the method that would be selected for a particular set of actual arguments).

Overall methods documentation is requested by calling the `?` operator with `methods` as the left-side argument and the name of the function as the right-side argument. For example,

```
methods ? initialize
```

asks for documentation on the methods for the [initialize](#) function.

Asking for documentation on a particular method is done by giving a function call expression as the right-hand argument to the `"?"` operator. There are two forms, depending on whether you prefer to give the class names for the arguments or expressions that you intend to use in the actual call.

If you planned to evaluate a function call, say `myFun(x, sqrt(wt))` and wanted to find out something about the method that would be used for this call, put the call on the right of the `"?"` operator:

```
?myFun(x, sqrt(wt))
```

A method will be selected, as it would be for the call itself, and documentation for that method will be requested. If `myFun` is not a generic function, ordinary documentation for the function will be requested.

If you know the actual classes for which you would like method documentation, you can supply these explicitly in place of the argument expressions. In the example above, if you want method documentation for the first argument having class "maybeNumber" and the second "logical", call the `"?"` operator, this time with a left-side argument `method`, and with a function call on the right using the class names as arguments:

```
method ? myFun("maybeNumber", "logical")
```

Once again, a method will be selected, this time corresponding to the specified classes, and method documentation will be requested. This version only works with generic functions.

The two forms each have advantages. The version with actual arguments doesn't require you to figure out (or guess at) the classes of the arguments. On the other hand, evaluating the arguments may take some time, depending on the example. The version with class names does require you to pick classes, but it's otherwise unambiguous. It has a subtler advantage, in that the classes supplied may be virtual classes, in which case no actual argument will have specifically this class. The class "maybeNumber", for example, might be a class union (see the example for [setClassUnion](#)).

In either form, methods will be selected as they would be in actual computation, including use of inheritance and group generic functions. See [selectMethod](#) for the details, since it is the function used to find the appropriate method.

## Writing Documentation for Methods

The on-line documentation for methods and classes uses some extensions to the R documentation format to implement the requests for class and method documentation described above. See the document *Writing R Extensions* for the available markup commands (you should have consulted this document already if you are at the stage of documenting your software).

In addition to the specific markup commands to be described, you can create an initial, overall file with a skeleton of documentation for the methods defined for a particular generic function:

```
promptMethods("myFun")
```

will create a file, 'myFun-methods.Rd' with a skeleton of documentation for the methods defined for function myFun. The output from `promptMethods` is suitable if you want to describe all or most of the methods for the function in one file, separate from the documentation of the generic function itself. Once the file has been filled in and moved to the 'man' subdirectory of your source package, requests for methods documentation will use that file, both for specific methods documentation as described above, and for overall documentation requested by

```
methods ? myFun
```

You are not required to use `promptMethods`, and if you do, you may not want to use the entire file created:

- If you want to document the methods in the file containing the documentation for the generic function itself, you can cut-and-paste to move the \alias lines and the Methods section from the file created by `promptMethods` to the existing file.
- On the other hand, if these are auxiliary methods, and you only want to document the added or modified software, you should strip out all but the relevant \alias lines for the methods of interest, and remove all but the corresponding \item entries in the Methods section. Note that in this case you will usually remove the first \alias line as well, since that is the marker for general methods documentation on this function (in the example, '\alias{myfun-methods}').

If you simply want to direct documentation for one or more methods to a particular R documentation file, insert the appropriate alias.

## Description

The “...” argument in R functions is treated specially, in that it matches zero, one or more actual arguments (and so, objects). A mechanism has been added to R to allow “...” as the signature of a generic function. Methods defined for such functions will be selected and called when *all* the arguments matching “...” are from the specified class or from some subclass of that class.

## Using “...” in a Signature

Beginning with version 2.8.0 of R, S4 methods can be dispatched (selected and called) corresponding to the special argument “...”. Currently, “...” cannot be mixed with other formal arguments: either the signature of the generic function is “...” only, or it does not contain “...”. (This restriction may be lifted in a future version.)

Given a suitable generic function, methods are specified in the usual way by a call to [setMethod](#). The method definition must be written expecting all the arguments corresponding to “...” to be from the class specified in the method’s signature, or from a class that extends that class (i.e., a subclass of that class).

Typically the methods will pass “...” down to another function or will create a list of the arguments and iterate over that. See the examples below.

When you have a computation that is suitable for more than one existing class, a convenient approach may be to define a union of these classes by a call to [setClassUnion](#). See the example below.

## Method Selection and Dispatch for “...”

See [Methods](#) for a general discussion. The following assumes you have read the “Method Selection and Dispatch” section of that documentation.

A method selecting on “...” is specified by a single class in the call to [setMethod](#). If all the actual arguments corresponding to “...” have this class, the corresponding method is selected directly.

Otherwise, the class of each argument and that class’ superclasses are computed, beginning with the first “...” argument. For the first argument, eligible methods are those for any of the classes. For each succeeding argument that introduces a class not considered previously, the eligible methods are further restricted to those matching the argument’s class or superclasses. If no further eligible classes exist, the iteration breaks out and the default method, if any, is selected.

At the end of the iteration, one or more methods may be eligible. If more than one, the selection looks for the method with the least distance to the actual arguments. For each argument, any inherited method corresponds to a distance, available from the `contains` slot of the class definition. Since the same class can arise for more than one argument, there may be several distances associated with it. Combining them is inevitably arbitrary: the current computation uses the minimum distance. Thus, for example, if a method matched one argument directly, one as first generation superclass and another as a second generation superclass, the distances are 0, 1 and 2. The current selection computation would use distance 0 for this method. In particular, this selection criterion tends to use a method that matches exactly one or more of the arguments’ class.

As with ordinary method selection, there may be multiple methods with the same distance. A warning message is issued and one of the methods is chosen (the first encountered, which in this case is rather arbitrary).

Notice that, while the computation examines all arguments, the essential cost of dispatch goes up with the number of *distinct* classes among the arguments, likely to be much smaller than the number of arguments when the latter is large.

## Implementation Details

Methods dispatching on “...” were introduced in version 2.8.0 of R. The initial implementation of the corresponding selection and dispatch is in an R function, for flexibility while the new mechanism is being studied. In this implementation, a local version of `setGeneric` is inserted in the generic function’s environment. The local version selects a method according to the criteria above and calls that method, from the environment of the generic function. This is slightly different from the action taken by the C implementation when “...” is not involved. Aside from the extra computing time required, the method is evaluated in a true function call, as opposed to the special context constructed by the C version (which cannot be exactly replicated in R code.) However, situations in which different computational results would be obtained have not been encountered so far, and seem very unlikely.

Methods dispatching on arguments other than “...” are *cached* by storing the inherited method in the table of all methods, where it will be found on the next selection with the same combination of classes in the actual arguments (but not used for inheritance searches). Methods based on “...” are also cached, but not found quite as immediately. As noted, the selected method depends only on the set of classes that occur in the “...” arguments. Each of these classes can appear one or more times, so many combinations of actual argument classes will give rise to the same effective signature. The selection computation first computes and sorts the distinct classes encountered. This gives a label that will be cached in the table of all methods, avoiding any further search for inherited classes after the first occurrence. A call to `showMethods` will expose such inherited methods.

The intention is that the “...” features will be added to the standard C code when enough experience with them has been obtained. It is possible that at the same time, combinations of “...” with other arguments in signatures may be supported.

## Examples

```
cc <- function(...)c(...)

setGeneric("cc")

setMethod("cc", "character", function(...)paste(...))

setClassUnion("Number", c("numeric", "complex"))

setMethod("cc", "Number", function(...) sum(...))

setClass("cdate", contains = "character", representation(date = "Date"))

setClass("vdate", contains = "vector", representation(date = "Date"))

cd1 <- new("cdate", "abcdef", date = Sys.Date())

cd2 <- new("vdate", "abcdef", date = Sys.Date())
```

```

stopifnot(identical(cc(letters, character(), cd1),
 paste(letters, character(), cd1))) # the "character" method

stopifnot(identical(cc(letters, character(), cd2),
 c(letters, character(), cd2)))
the default, because "vdate" doesn't extend "character"

stopifnot(identical(cc(1:10, 1+1i), sum(1:10, 1+1i))) # the "Number" method

stopifnot(identical(cc(1:10, 1+1i, TRUE), c(1:10, 1+1i, TRUE))) # the default

stopifnot(identical(cc(), c())) # no arguments implies the default method

setGeneric("numMax", function(...)standardGeneric("numMax"))

setMethod("numMax", "numeric", function(...)max(...))
won't work for complex data
setMethod("numMax", "Number", function(...) paste(...))
should not be selected w/o complex args

stopifnot(identical(numMax(1:10, pi, 1+1i), paste(1:10, pi, 1+1i)))
stopifnot(identical(numMax(1:10, pi, 1), max(1:10, pi, 1)))

try(numMax(1:10, pi, TRUE)) # should be an error: no default method

A generic version of paste(), dispatching on the "..." argument:
setGeneric("paste", signature = "...")

setMethod("paste", "Number", function(..., sep, collapse) c(...))

stopifnot(identical(paste(1:10, pi, 1), c(1:10, pi, 1)))

```

environment-class      *Class "environment"*

## Description

A formal class for R environments.

## Objects from the Class

Objects can be created by calls of the form `new("environment", ...)`. The arguments in ..., if any, should be named and will be assigned to the newly created environment.

## Methods

**coerce** `signature(from = "ANY", to = "environment")`: calls `as.environment`.

**initialize** `signature(object = "environment")`: Implements the assignments in the new environment. Note that the object argument is ignored; a new environment is *always* created, since environments are not protected by copying.

## Description

Support Class to Implement R Objects using Reference Semantics

### NOTE:

The software described here is an initial version. The eventual goal is to support reference-style classes with software in R itself or using inter-system interfaces. The current implementation (R version 2.12.0) is preliminary and subject to change, and currently includes only the R-only implementation. Developers are encouraged to experiment with the software, but the description here is more than usually subject to change.

## Purpose of the Class

This class implements basic reference-style semantics for R objects. Objects normally do not come directly from this class, but from subclasses defined by a call to [setRefClass](#). The documentation below is technical background describing the implementation, but applications should use the interface documented under [setRefClass](#), in particular the \$ operator and field accessor functions as described there.

## A Basic Reference Class

The design of reference classes for R divides those classes up according to the mechanism used for implementing references, fields, and class methods. Each version of this mechanism is defined by a *basic reference class*, which must implement a set of methods and provide some further information used by [setRefClass](#).

The required methods are for operators \$ and \$<- to get and set a field in an object, and for [initialize](#) to initialize objects.

To support these methods, the basic reference class needs to have some implementation mechanism to store and retrieve data from fields in the object. The mechanism needs to be consistent with reference semantics; that is, changes made to the contents of an object are global, seen by any code accessing that object, rather than only local to the function call where the change takes place. As described below, class envRefClass implements reference semantics through specialized use of [environment](#) objects. Other basic reference classes may use an interface to a language such as Java or C++ using reference semantics for classes.

Usually, the R user will be able to invoke class methods on the class, using the \$ operator. The basic reference class method for \$ needs to make this possible. Essentially, the operator must return an R function corresponding to the object and the class method name.

Class methods may include an implementation of data abstraction, in the sense that fields are accessed by “get” and “set” methods. The basic reference class provides this facility by setting the “fieldAccessorGenerator” slot in its definition to a function of one variable. This function will be called by [setRefClass](#) with the vector of field names as arguments. The generator function must return a list of defined accessor functions. An element corresponding to a get operation is invoked with no arguments and should extract the corresponding field; an element for a set operation will

be invoked with a single argument, the value to be assigned to the field. The implementation needs to supply the object, since that is not an argument in the method invocation. The mechanism used currently by `envRefClass` is described below.

### Support Classes

Two virtual classes are supplied to test for reference objects: `is(x, "refClass")` tests whether `x` comes from a class defined using the reference class mechanism described here; `is(x, "refObject")` tests whether the object has reference semantics generally, including the previous classes and also classes inheriting from the R types with reference semantics, such as "environment".

Installed class methods are "classMethodDefinition" objects, with slots that identify the name of the function as a class method and the other class methods called from this method. The latter information is determined heuristically when the class is defined by using the `codetools` recommended package. This package must be installed when reference classes are defined, but is not needed in order to use existing reference classes.

evalSource

*Use Function Definitions from a Source File without Reinstalling a Package*

---

### Description

Definitions of functions and/or methods from a source file are inserted into a package, using the `trace` mechanism. Typically, this allows testing or debugging modified versions of a few functions without reinstalling a large package.

### Usage

```
evalSource(source, package = "", lock = TRUE, cache = FALSE)

insertSource(source, package = "", functions = , methods = ,
 force =)
```

### Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| source  | A file to be parsed and evaluated by <code>evalSource</code> to find the new function and method definitions.<br><br>The argument to <code>insertSource</code> can be an object of class "sourceEnvironment" returned from a previous call to <code>evalSource</code> . If a file name is passed to <code>insertSource</code> it calls <code>evalSource</code> to obtain the corresponding object. See the section on the class for details. |
| package | Optionally, the name of the package to which the new code corresponds and into which it will be inserted. Although the computations will attempt to infer the package if it is omitted, the safe approach is to supply it. In the case of a package that is not attached to the search list, the package name must be supplied.                                                                                                              |

**functions, methods**

Optionally, the character-string names of the functions to be used in the insertion. Names supplied in the `functions` argument are expected to be defined as functions in the source. For names supplied in the `methods` argument, a table of methods is expected (as generated by calls to `setMethod`, see the details section); methods from this table will be inserted by `insertSource`. In both cases, the revised function or method is inserted only if it differs from the version in the corresponding package as loaded.

If what is omitted, the results of evaluating the source file will be compared to the contents of the package (see the details section).

**lock, cache**

Optional arguments to control the actions taken by `evalSource`. If `lock` is TRUE, the environment in the object returned will be locked, and so will all its bindings. If `cache` is FALSE, the normal caching of method and class definitions will be suppressed during evaluation of the source file.

The default settings are generally recommended, the `lock` to support the credibility of the object returned as a snapshot of the source file, and the second so that method definitions can be inserted later by `insertSource` using the trace mechanism.

**force**

If FALSE, only functions currently in the environment will be redefined, using `trace`. If TRUE, other objects/functions will be simply assigned. By default, TRUE if neither the `functions` nor the `methods` argument is supplied.

**Details**

The source file is parsed and evaluated, suppressing by default the actual caching of method and class definitions contained in it, so that functions and methods can be tested out in a reversible way. The result, if all goes well, is an environment containing the assigned objects and metadata corresponding to method and class definitions in the source file.

From this environment, the objects are inserted into the package, into its namespace if it has one, for use during the current session or until reverting to the original version by a call to `untrace`. The insertion is done by calls to the internal version of `trace`, to make reversion possible.

Because the trace mechanism is used, only function-type objects will be inserted, functions themselves or S4 methods.

When the `functions` and `methods` arguments are both omitted, `insertSource` selects all suitable objects from the result of evaluating the source file.

In all cases, only objects in the source file that differ from the corresponding objects in the package are inserted. The definition of “differ” is that either the argument list (including default expressions) or the body of the function is not identical. Note that in the case of a method, there need be no specific method for the corresponding signature in the package: the comparison is made to the method that would be selected for that signature.

Nothing in the computation requires that the source file supplied be the same file as in the original package source, although that case is both likely and sensible if one is revising the package. Nothing in the computations compares source files: the objects generated by evaluating source are compared as objects to the content of the package.

**Value**

An object from class “`sourceEnvironment`”, a subclass of “`environment`” (see the section on the class). The environment contains the versions of *all* object resulting from evaluation of the source file. The class also has slots for the time of creation, the source file and the package name. Future extensions may use these objects for versioning or other code tools.

The object returned can be used in debugging (see the section on that topic) or as the source argument in a future call to `insertSource`. If only some of the revised functions were inserted in the first call, others can be inserted in a later call without re-evaluating the source file, by supplying the environment and optionally suitable functions and/or methods argument.

### Debugging

Once a function or method has been inserted into a package by `insertSource`, it can be studied by the standard debugging tools; for example, `debug` or the various versions of `trace`.

Calls to `trace` should take the extra argument `edit = env`, where `env` is the value returned by the call to `evalSource`. The trace mechanism has been used to install the revised version from the source file, and supplying the argument ensures that it is this version, not the original, that will be traced. See the example below.

To turn tracing off, but retain the source version, use `trace(x, edit = env)` as in the example. To return to the original version from the package, use `untrace(x)`.

### Class "sourceEnvironment"

Objects from this class can be treated as environments, to extract the version of functions and methods generated by `evalSource`. The objects also have the following slots:

`packageName`: The character-string name of the package to which the source code corresponds.  
`dateCreated`: The date and time that the source file was evaluated (usually from a call to `Sys.time`).  
`sourceFile`: The character-string name of the source file used.  
Note that using the environment does not change the `dateCreated`.

### See Also

`trace` for the underlying mechanism, and also for the `edit=` argument that can be used for somewhat similar purposes; that function and also `debug` and `setBreakpoint`, for techniques more oriented to traditional debugging styles. The present function is directly intended for the case that one is modifying some of the source for an existing package, although it can be used as well by inserting debugging code in the source (more useful if the debugging involved is non-trivial). As noted in the details section, the source file need not be the same one in the original package source.

### Examples

```
Not run:
Suppose package P0 has a source file "all.R"
First, evaluate the source, and from it
insert the revised version of methods for summary()
env <- insertSource("./P0/R/all.R", package = "P0",
 methods = "summary")
now test one of the methods, tracing the version from the source
trace("summary", signature = "myMat", browser, edit = env)
After testing, remove the browser() call but keep the source
trace("summary", signature = "myMat", edit = env)
Now insert all the (other) revised functions and methods
without re-evaluating the source file.
The package name is included in the object env.
insertSource(env)

End(Not run)
```

**findClass***Computations with Classes*

---

**Description**

Functions to find and manipulate class definitions.

**Usage**

```
removeClass(Class, where)

isClass(Class, formal=TRUE, where)

getClasses(where, inherits = missing(where))

findClass(Class, where, unique = "")

resetClass(Class, classDef, where)

sealClass(Class, where)
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Class    | character string name for the class. The functions will usually take a class definition instead of the string. To restrict the class to those defined in a particular package, set the <a href="#">packageSlot</a> of the character string.                                                                                                                                                                                                                       |
| where    | the <a href="#">environment</a> in which to modify or remove the definition. Defaults to the top-level environment of the calling function (the global environment for ordinary computations, but the environment or namespace of a package in the source for a package).<br>When searching for class definitions, where defines where to do the search, and the default is to search from the top-level environment or namespace of the caller to this function. |
| unique   | if <code>findClass</code> expects a unique location for the class, unique is a character string explaining the purpose of the search (and is used in warning and error messages). By default, multiple locations are possible and the function always returns a list.                                                                                                                                                                                             |
| inherits | in a call to <code>getClasses</code> , should the value returned include all parent environments of where, or that environment only? Defaults to TRUE if where is omitted, and to FALSE otherwise.                                                                                                                                                                                                                                                                |
| formal   | Should a formal definition be required?                                                                                                                                                                                                                                                                                                                                                                                                                           |
| classDef | For <code>removeClass</code> , the optional class definition (but usually it's better for Class to be the class definition, and to omit classDef).                                                                                                                                                                                                                                                                                                                |

**Details**

These are the functions that test and manipulate formal class definitions. Brief documentation is provided below. See the references for an introduction and for more details.

**removeClass:** Remove the definition of this class, from the environment where if this argument is supplied; if not, `removeClass` will search for a definition, starting in the top-level environment of the call to `removeClass`, and remove the (first) definition found.

**isClass:** Is this the name of a formally defined class? (Argument `formal` is for compatibility and is ignored.)

**getClasses:** The names of all the classes formally defined on `where`. If called with no argument, all the classes visible from the calling function (if called from the top-level, all the classes in any of the environments on the search list). The `inherits` argument can be used to search a particular environment and all its parents, but usually the default setting is what you want.

**findClass:** The list of environments or positions on the search list in which a class definition of `Class` is found. If `where` is supplied, this is an environment (or namespace) from which the search takes place; otherwise the top-level environment of the caller is used. If `unique` is supplied as a character string, `findClass` returns a single environment or position. By default, it always returns a list. The calling function should select, say, the first element as a position or environment for functions such as `get`.

If `unique` is supplied as a character string, `findClass` will warn if there is more than one definition visible (using the string to identify the purpose of the call), and will generate an error if no definition can be found.

**resetClass:** Reset the internal definition of a class. Causes the complete definition of the class to be re-computed, from the representation and superclasses specified in the original call to `setClass`.

This function is called when aspects of the class definition are changed. You would need to call it explicitly if you changed the definition of a class that this class extends (but doing that in the middle of a session is living dangerously, since it may invalidate existing objects).

**sealClass:** Seal the current definition of the specified class, to prevent further changes. It is possible to seal a class in the call to `setClass`, but sometimes further changes have to be made (e.g., by calls to `setIs`). If so, call `sealClass` after all the relevant changes have been made.

findMethods

*Description of the Methods Defined for a Generic Function*

---

## Description

The function `findMethods` converts the methods defined in a table for a generic function (as used for selection of methods) into a list, for study or display. The list is actually from the class `listOfMethods` (see the section describing the class, below).

The list will be limited to the methods defined in environment where if that argument is supplied and limited to those including one or more of the specified classes in the method signature if that argument is supplied.

To see the actual table (an environment) used for methods dispatch, call [getMethodsForDispatch](#). The names of the list returned by *findMethods* are the names of the objects in the table.

The function *findMethodSignatures* returns a character matrix whose rows are the class names from the signature of the corresponding methods; it operates either from a list returned by *findMethods*, or by computing such a list itself, given the same arguments as *findMethods*.

The function *hasMethods* returns TRUE or FALSE according to whether there is a non-empty table of methods for function f in the environment or search position where (or for the generic function generally if where is missing).

The deprecated function *getMethods* is an older alternative to *findMethods*, returning information in the form of an object of class *MethodsList*, previously used for method dispatch. It is not recommended, since this class of objects is deprecated generally and will disappear in a future version of R.

## Usage

```
findMethods(f, where, classes = character(), inherited = FALSE,
 package = "")

findMethodSignatures(..., target = TRUE, methods =)

hasMethods(f, where, package)

DEPRECATED
getMethods(f, where, table = FALSE)
```

## Arguments

|                  |                                                                                                                                                                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>f</i>         | A generic function or the character-string name of one.                                                                                                                                                                                                                          |
| <i>where</i>     | Optionally, an environment or position on the search list to look for methods metadata.                                                                                                                                                                                          |
|                  | If where is missing, <i>findMethods</i> uses the current table of methods in the generic function itself, and <i>hasMethods</i> looks for metadata anywhere in the search list.                                                                                                  |
| <i>table</i>     | If TRUE in a call to <i>getMethods</i> the returned value is the table used for dispatch, including inherited methods discovered to date. Used internally, but since the default result is the now unused <i>mlist</i> object, the default will likely be changed at some point. |
| <i>classes</i>   | If supplied, only methods whose signatures contain at least one of the supplied classes will be included in the value returned.                                                                                                                                                  |
| <i>inherited</i> | Logical flag; if TRUE, the table of all methods, inherited or defined directly, will be used; otherwise, only the methods explicitly defined. Option TRUE is meaningful only if where is missing.                                                                                |
| ...              | In the call to <i>findMethodSignatures</i> , any arguments that might be given to <i>findMethods</i> .                                                                                                                                                                           |
| <i>target</i>    | Optional flag to <i>findMethodSignatures</i> ; if TRUE, the signatures used are the target signatures (the classes for which the method will be selected); if FALSE, they will be the signatures defined. The difference is only meaningful if <i>inherited</i> is TRUE.         |

|         |                                                                                                                                                                                                                                                                                     |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| methods | In the call to <code>findMethodSignatures</code> , an optional list of methods, presumably returned by a previous call to <code>findMethods</code> . If missing, that function will be called with the ... arguments.                                                               |
| package | In a call to <code>hasMethods</code> , the package name for the generic function (e.g., "base" for primitives). If missing this will be inferred either from the "package" attribute of the function name, if any, or from the package slot of the generic function. See 'Details'. |

### Details

The functions obtain a table of the defined methods, either from the generic function or from the stored metadata object in the environment specified by `where`. In a call to `getMethods`, the information in the table is converted as described above to produce the returned value, except with the `table` argument.

Note that `hasMethods`, but not the other functions, can be used even if no generic function of this name is currently found. In this case `package` must either be supplied as an argument or included as an attribute of `f`, since the package name is part of the identification of the methods tables.

### The Class for lists of methods

The class "`listOfMethods`" returns the methods as a named list of method definitions (or a primitive function, see the slot documentation below). The names are the strings used to store the corresponding objects in the environment from which method dispatch is computed. The current implementation uses the names of the corresponding classes in the method signature, separated by "#" if more than one argument is involved in the signature.

### Slots

**.Data:** Object of class "list" The method definitions.

Note that these may include the primitive function itself as default method, when the generic corresponds to a primitive. (Basically, because primitive functions are abnormal R objects, which cannot currently be extended as method definitions.) Computations that use the returned list to derive other information need to take account of this possibility. See the implementation of `findMethodSignatures` for an example.

**arguments:** Object of class "character". The names of the formal arguments in the signature of the generic function.

**signatures:** Object of class "list". A list of the signatures of the individual methods. This is currently the result of splitting the names according to the "#" separator.

If the object has been constructed from a table, as when returned by `findMethods`, the signatures will all have the same length. However, a list rather than a character matrix is used for generality. Calling `findMethodSignatures` as in the example below will always convert to the matrix form.

**generic:** Object of class "genericFunction". The generic function corresponding to these methods. There are plans to generalize this slot to allow reference to the function.

**names:** Object of class "character". The names as noted are the class names separated by "#".

### Extends

Class "`namedList`", directly.

Class "`list`", by class "`namedList`", distance 2.

Class "`vector`", by class "`namedList`", distance 3.

**Examples**

```
mm <- findMethods("Ops")
findMethodSignatures(methods = mm)
```

**fixPre1.8**

*Fix Objects Saved from R Versions Previous to 1.8*

**Description**

Beginning with R version 1.8.0, the class of an object contains the identification of the package in which the class is defined. The function `fixPre1.8` fixes and re-assigns objects missing that information (typically because they were loaded from a file saved with a previous version of R.)

**Usage**

```
fixPre1.8(names, where)
```

**Arguments**

|                    |                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>names</code> | Character vector of the names of all the objects to be fixed and re-assigned.                                                                                                                                        |
| <code>where</code> | The environment from which to look for the objects, and for class definitions. Defaults to the top environment of the call to <code>fixPre1.8</code> , the global environment if the function is used interactively. |

**Details**

The named object will be saved where it was found. Its class attribute will be changed to the full form required by R 1.8; otherwise, the contents of the object should be unchanged.

Objects will be fixed and re-assigned only if all the following conditions hold:

1. The named object exists.
2. It is from a defined class (not a basic datatype which has no actual class attribute).
3. The object appears to be from an earlier version of R.
4. The class is currently defined.
5. The object is consistent with the current class definition.

If any condition except the second fails, a warning message is generated.

Note that `fixPre1.8` currently fixes *only* the change in class attributes. In particular, it will not fix binary versions of packages installed with earlier versions of R if these use incompatible features. Such packages must be re-installed from source, which is the wise approach always when major version changes occur in R.

**Value**

The names of all the objects that were in fact re-assigned.

---

**genericFunction-class Generic Function Objects**

---

## Description

Generic functions (objects from or extending class `genericFunction`) are extended function objects, containing information used in creating and dispatching methods for this function. They also identify the package associated with the function and its methods.

## Objects from the Class

Generic functions are created and assigned by `setGeneric` or `setGroupGeneric` and, indirectly, by `setMethod`.

As you might expect `setGeneric` and `setGroupGeneric` create objects of class "genericFunction" and "groupGenericFunction" respectively.

## Slots

**.Data:** Object of class "function", the function definition of the generic, usually created automatically as a call to `standardGeneric`.

**generic:** Object of class "character", the name of the generic function.

**package:** Object of class "character", the name of the package to which the function definition belongs (and *not* necessarily where the generic function is stored). If the package is not specified explicitly in the call to `setGeneric`, it is usually the package on which the corresponding non-generic function exists.

**group:** Object of class "list", the group or groups to which this generic function belongs. Empty by default.

**valueClass:** Object of class "character"; if not an empty character vector, identifies one or more classes. It is asserted that all methods for this function return objects from these class (or from classes that extend them).

**signature:** Object of class "character", the vector of formal argument names that can appear in the signature of methods for this generic function. By default, it is all the formal arguments, except for .... Order matters for efficiency: the most commonly used arguments in specifying methods should come first.

**default:** Object of class "optionalMethod" (a union of classes "function" and "NULL"), containing the default method for this function if any. Generated automatically and used to initialize method dispatch.

**skeleton:** Object of class "call", a slot used internally in method dispatch. Don't expect to use it directly.

## Extends

Class "function", from data part.

Class "OptionalMethods", by class "function".

Class "PossibleMethod", by class "function".

## Methods

Generic function objects are used in the creation and dispatch of formal methods; information from the object is used to create methods list objects and to merge or update the existing methods for this generic.

## Description

The functions documented here manage collections of methods associated with a generic function, as well as providing information about the generic functions themselves.

## Usage

```
isGeneric(f, where, fdef, getName = FALSE)
isGroup(f, where, fdef)
removeGeneric(f, where)

dumpMethod(f, signature, file, where, def)
findFunction(f, generic = TRUE, where = topenv(parent.frame()))
dumpMethods(f, file, signature, methods, where)
signature(...)

removeMethods(f, where = topenv(parent.frame()), all = missing(where))

setReplaceMethod(f, ..., where = topenv(parent.frame()))

getGenerics(where, searchForm = FALSE)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>         | The character string naming the function.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>where</code>     | The environment, namespace, or search-list position from which to search for objects. By default, start at the top-level environment of the calling function, typically the global environment (i.e., use the search list), or the namespace of a package from which the call came. It is important to supply this argument when calling any of these functions indirectly. With package namespaces, the default is likely to be wrong in such calls. |
| <code>signature</code> | The class signature of the relevant method. A signature is a named or unnamed vector of character strings. If named, the names must be formal argument names for the generic function. Signatures are matched to the arguments specified in the signature slot of the generic function (see the Details section of the <a href="#">setMethod</a> documentation).                                                                                      |
|                        | The <code>signature</code> argument to <code>dumpMethods</code> is ignored (it was used internally in previous implementations).                                                                                                                                                                                                                                                                                                                      |
| <code>file</code>      | The file or connection on which to dump method definitions.                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>def</code>       | The function object defining the method; if omitted, the current method definition corresponding to the signature.                                                                                                                                                                                                                                                                                                                                    |

|            |                                                                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ...        | Named or unnamed arguments to form a signature.                                                                                                                                                      |
| generic    | In testing or finding functions, should generic functions be included. Supply as FALSE to get only non-generic functions.                                                                            |
| fdef       | Optional, the generic function definition.<br>Usually omitted in calls to <code>isGeneric</code>                                                                                                     |
| getName    | If TRUE, <code>isGeneric</code> returns the name of the generic. By default, it returns TRUE.                                                                                                        |
| methods    | The methods object containing the methods to be dumped. By default, the methods defined for this generic (optionally on the specified where location).                                               |
| all        | in <code>removeMethods</code> , logical indicating if all (default) or only the first method found should be removed.                                                                                |
| searchForm | In <code>getGenerics</code> , if TRUE, the package slot of the returned result is in the form used by <code>search()</code> , otherwise as the simple package name (e.g., "package:base" vs "base"). |

## Summary of Functions

`isGeneric`: Is there a function named `f`, and if so, is it a generic?

The `getName` argument allows a function to find the name from a function definition. If it is TRUE then the name of the generic is returned, or FALSE if this is not a generic function definition.

The behavior of `isGeneric` and `getGeneric` for primitive functions is slightly different. These functions don't exist as formal function objects (for efficiency and historical reasons), regardless of whether methods have been defined for them. A call to `isGeneric` tells you whether methods have been defined for this primitive function, anywhere in the current search list, or in the specified position where. In contrast, a call to `getGeneric` will return what the generic for that function would be, even if no methods have been currently defined for it.

`removeGeneric`, `removeMethods`: Remove all the methods for the generic function of this name.

In addition, `removeGeneric` removes the function itself; `removeMethods` restores the non-generic function which was the default method. If there was no default method, `removeMethods` leaves a generic function with no methods.

`standardGeneric`: Dispatches a method from the current function call for the generic function `f`. It is an error to call `standardGeneric` anywhere except in the body of the corresponding generic function.

Note that `standardGeneric` is a primitive function in the `base` package for efficiency reasons, but rather documented here where it belongs naturally.

`dumpMethod`: Dump the method for this generic function and signature.

`findFunction`: return a list of either the positions on the search list, or the current top-level environment, on which a function object for name exists. The returned value is *always* a list, use the first element to access the first visible version of the function. See the example.

*NOTE:* Use this rather than `find` with mode="function", which is not as meaningful, and has a few subtle bugs from its use of regular expressions. Also, `findFunction` works correctly in the code for a package when attaching the package via a call to `library`.

`dumpMethods`: Dump all the methods for this generic.

`signature`: Returns a named list of classes to be matched to arguments of a generic function.

`getGenerics`: returns the names of the generic functions that have methods defined on where; this argument can be an environment or an index into the search list. By default, the whole search list is used.

The methods definitions are stored with package qualifiers; for example, methods for function "initialize" might refer to two different functions of that name, on different packages. The package names corresponding to the method list object are contained in the slot package of the returned object. The form of the returned name can be plain (e.g., "base"), or in the form used in the search list ("package:base") according to the value of searchForm

## Details

**setGeneric:** If there is already a non-generic function of this name, it will be used to define the generic unless def is supplied, and the current function will become the default method for the generic.

If def is supplied, this defines the generic function, and no default method will exist (often a good feature, if the function should only be available for a meaningful subset of all objects).

Arguments group and valueClass are retained for consistency with S-Plus, but are currently not used.

**isGeneric:** If the fdef argument is supplied, take this as the definition of the generic, and test whether it is really a generic, with f as the name of the generic. (This argument is not available in S-Plus.)

**removeGeneric:** If where supplied, just remove the version on this element of the search list; otherwise, removes the first version encountered.

**standardGeneric:** Generic functions should usually have a call to standardGeneric as their entire body. They can, however, do any other computations as well.

The usual setGeneric (directly or through calling setMethod) creates a function with a call to standardGeneric.

**dumpMethod:** The resulting source file will recreate the method.

**findFunction:** If generic is FALSE, ignore generic functions.

**dumpMethods:** If signature is supplied only the methods matching this initial signature are dumped. (This feature is not found in S-Plus: don't use it if you want compatibility.)

**signature:** The advantage of using signature is to provide a check on which arguments you meant, as well as clearer documentation in your method specification. In addition, signature checks that each of the elements is a single character string.

**removeMethods:** Returns TRUE if f was a generic function, FALSE (silently) otherwise.

If there is a default method, the function will be re-assigned as a simple function with this definition. Otherwise, the generic function remains but with no methods (so any call to it will generate an error). In either case, a following call to setMethod will consistently re-establish the same generic function as before.

## Examples

```

require(stats) # for lm

get the function "myFun" -- throw an error if 0 or > 1 versions visible:
findFuncStrict <- function(fName) {
 allF <- findFunction(fName)
 if(length(allF) == 0)
 stop("No versions of ", fName, " visible")
 else if(length(allF) > 1)
 stop(fName, " is ambiguous: ", length(allF), " versions")
 else
 get(fName, allF[[1]])
}

try(findFuncStrict("myFun"))# Error: no version
lm <- function(x) x+1
try(findFuncStrict("lm"))# Error: 2 versions
findFuncStrict("findFuncStrict")# just 1 version
rm(lm)

method dumping -----
setClass("A", representation(a="numeric"))
setMethod("plot", "A", function(x,y,...){ cat("A meth\n") })
dumpMethod("plot","A", file="")
Not run:
setMethod("plot", "A",
function (x, y, ...)
{
 cat("AAAAA\n")
}
)

End(Not run)
tmp <- tempfile()
dumpMethod("plot","A", file=tmp)
now remove, and see if we can parse the dump
stopifnot(removeMethod("plot", "A"))
source(tmp)
stopifnot(isgetMethod("plot", "A"), "MethodDefinition"))

same with dumpMethods() :
setClass("B", contains="A")
setMethod("plot", "B", function(x,y,...){ cat("B ...\\n") })
dumpMethods("plot", file=tmp)
stopifnot(removeMethod("plot", "A"),
 removeMethod("plot", "B"))
source(tmp)
stopifnot(isgetMethod("plot", "A"), "MethodDefinition"),
 isgetMethod("plot", "B"), "MethodDefinition"))

```

## Description

Get the definition of a class.

## Usage

```
getClass(Class, .Force = FALSE, where)
getClassDef(Class, where, package, inherits = TRUE)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Class</code>    | the character-string name of the class, often with a "package" attribute as noted below under <code>package</code> .                                                                                                                                                                                                                                                                                                                             |
| <code>.Force</code>   | if TRUE, return NULL if the class is undefined; otherwise, an undefined class results in an error.                                                                                                                                                                                                                                                                                                                                               |
| <code>where</code>    | environment from which to begin the search for the definition; by default, start at the top-level (global) environment and proceed through the search list.                                                                                                                                                                                                                                                                                      |
| <code>package</code>  | the name of the package asserted to hold the definition. If it is a non-empty string it is used instead of <code>where</code> , as the first place to look for the class. Note that the package must be loaded but need not be attached. By default, the package attribute of the <code>Class</code> argument is used, if any. There will usually be a package attribute if <code>Class</code> comes from <code>class(x)</code> for some object. |
| <code>inherits</code> | Should the class definition be retrieved from any enclosing environment and also from the cache? If FALSE only a definition in the environment <code>where</code> will be returned.                                                                                                                                                                                                                                                              |

## Details

Class definitions are stored in metadata objects in a package namespace or other environment where they are defined. When packages are loaded, the class definitions in the package are cached in an internal table. Therefore, most calls to `getClassDef` will find the class in the cache or fail to find it at all, unless `inherits` is FALSE, in which case only the environment(s) defined by `package` or `where` are searched.

The class cache allows for multiple definitions of the same class name in separate environments, with of course the limitation that the package attribute or package name must be provided in the call to

## Value

The object defining the class. If the class definition is not found, `getClassDef` returns NULL, while `getClass`, which calls `getClassDef`, either generates an error or, if `.Force` is TRUE, returns a simple definition for the class. The latter case is used internally, but is not typically sensible in user code.

The non-null returned value is an object of class `classRepresentation`. For all reasonable purposes, use this object only to extract information, rather than trying to modify it: Use functions such as `setClass` and `setIs` to create or modify class definitions.

[Classes](#), [setClass](#), [isClass](#).

**Examples**

```
getClass("numeric") ## a built in class

cld <- getClass("thisIsAnUndefinedClass", .Force = TRUE)
cld ## a NULL prototype
If you are really curious:
utils::str(cld)
Whereas these generate errors:
try(getClass("thisIsAnUndefinedClass"))
try(getClassDef("thisIsAnUndefinedClass"))
```

---

getMethod

*Get or Test for the Definition of a Method*

---

**Description**

Functions to look for a method corresponding to a given generic function and signature. The functions `getMethod` and `selectMethod` return the method; the functions `existsMethod` and `hasMethod` test for its existence. In both cases the first function only gets direct definitions and the second uses inheritance. In all cases, the search is in the generic function itself or in the package/environment specified by argument `where`.

The function `findMethod` returns the package(s) in the search list (or in the packages specified by the `where` argument) that contain a method for this function and signature.

**Usage**

```
getMethod(f, signature=character(), where, optional = FALSE,
 mlist, fdef)

existsMethod(f, signature = character(), where)

findMethod(f, signature, where)

selectMethod(f, signature, optional = FALSE, useInherited = ,
 mlist = , fdef = , verbose = , doCache =)

hasMethod(f, signature=character(), where)
```

**Arguments**

- |                        |                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>         | A generic function or the character-string name of one.                                                                                          |
| <code>signature</code> | the signature of classes to match to the arguments of <code>f</code> . See the details below.                                                    |
| <code>where</code>     | The position or environment in which to look for the method(s): by default, the table of methods defined in the generic function itself is used. |

|                                                          |                                                                                                                                                                                                                         |
|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| optional                                                 | If the selection in <code>selectMethod</code> does not find a valid method an error is generated, unless this argument is TRUE. In that case, the value returned is NULL if no method matches.                          |
| <code>mlist, fdef, useInherited, verbose, doCache</code> | Optional arguments to <code>getMethod</code> and <code>selectMethod</code> for internal use. Avoid these: some will work as expected and others will not, and none of them is required for normal use of the functions. |

## Details

The `signature` argument specifies classes, corresponding to formal arguments of the generic function; to be precise, to the `signature` slot of the generic function object. The argument may be a vector of strings identifying classes, and may be named or not. Names, if supplied, match the names of those formal arguments included in the signature of the generic. That signature is normally all the arguments except .... However, generic functions can be specified with only a subset of the arguments permitted, or with the signature taking the arguments in a different order.

It's a good idea to name the arguments in the signature to avoid confusion, if you're dealing with a generic that does something special with its signature. In any case, the elements of the signature are matched to the formal signature by the same rules used in matching arguments in function calls (see [match.call](#)).

The strings in the signature may be class names, "missing" or "ANY". See [Methods](#) for the meaning of these in method selection. Arguments not supplied in the signature implicitly correspond to class "ANY"; in particular, giving an empty signature means to look for the default method.

A call to `getMethod` returns the method for a particular function and signature. As with other `get` functions, argument `where` controls where the function looks (by default anywhere in the search list) and argument `optional` controls whether the function returns NULL or generates an error if the method is not found. The search for the method makes no use of inheritance.

The function `selectMethod` also looks for a method given the function and signature, but makes full use of the method dispatch mechanism; i.e., inherited methods and group generics are taken into account just as they would be in dispatching a method for the corresponding signature, with the one exception that conditional inheritance is not used. Like `getMethod`, `selectMethod` returns NULL or generates an error if the method is not found, depending on the argument `optional`.

The functions `existsMethod` and `hasMethod` return TRUE or FALSE according to whether a method is found, the first corresponding to `getMethod` (no inheritance) and the second to `selectMethod`.

## Value

The call to `selectMethod` or `getMethod` returns the selected method, if one is found. (This class extends function, so you can use the result directly as a function if that is what you want.) Otherwise an error is thrown if `optional` is FALSE and NULL is returned if `optional` is TRUE.

The returned method object is a [MethodDefinition](#) object, *except* that the default method for a primitive function is required to be the primitive itself. Note therefore that the only reliable test that the search failed is `is.null()`.

## Examples

```
setGeneric("testFun", function(x)standardGeneric("testFun"))
setMethod("testFun", "numeric", function(x)x+1)
hasMethod("testFun", "numeric")
Not run: [1] TRUE
hasMethod("testFun", "integer") #inherited
Not run: [1] TRUE
existsMethod("testFun", "integer")
Not run: [1] FALSE
hasMethod("testFun") # default method
Not run: [1] FALSE
hasMethod("testFun", "ANY")
Not run: [1] FALSE
```

getPackageName

*The Name associated with a Given Package*

## Description

The functions below produce the package associated with a particular environment or position on the search list, or of the package containing a particular function. They are primarily used to support computations that need to differentiate objects on multiple packages.

## Usage

```
getPackageName(where, create = TRUE)
setPackageName(pkg, env)

packageSlot(object)
packageSlot(object) <- value
```

## Arguments

|          |                                                                                                                                                                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| where    | the environment or position on the search list associated with the desired package.                                                                                                                                                                                             |
| object   | object providing a character string name, plus the package in which this object is to be found.                                                                                                                                                                                 |
| value    | the name of the package.                                                                                                                                                                                                                                                        |
| create   | flag, should a package name be created if none can be inferred? If TRUE and no non-empty package name is found, the current date and time are used as a package name, and a warning is issued. The created name is stored in the environment if that environment is not locked. |
| pkg, env | make the string in pkg the internal package name for all computations that set class and method definitions in environment env.                                                                                                                                                 |

## Details

Package names are normally installed during loading of the package, by the `INSTALL` script or by the `library` function. (Currently, the name is stored as the object `.packageName` but don't trust this for the future.)

## Value

`getPackageName` returns the character-string name of the package (without the extraneous "package:" found in the search list).

`packageSlot` returns or sets the package name slot (currently an attribute, not a formal slot, but this may change someday).

`setPackageName` can be used to establish a package name in an environment that would otherwise not have one. This allows you to create classes and/or methods in an arbitrary environment, but it is usually preferable to create packages by the standard R programming tools (`package.skeleton`, etc.).

## See Also

[search](#), `packageName`

## Examples

```
all the following usually return "base"
getPackageName(length(search()))
getPackageName(baseenv())
getPackageName(asNamespace("base"))
getPackageName("package:base")
```

hasArg

*Look for an Argument in the Call*

## Description

Returns TRUE if name corresponds to an argument in the call, either a formal argument to the function, or a component of ..., and FALSE otherwise.

## Usage

`hasArg(name)`

## Arguments

|      |                                                                            |
|------|----------------------------------------------------------------------------|
| name | The name of a potential argument, as an unquoted name or character string. |
|------|----------------------------------------------------------------------------|

## Details

The expression `hasArg(x)`, for example, is similar to `!missing(x)`, with two exceptions. First, `hasArg` will look for an argument named `x` in the call if `x` is not a formal argument to the calling function, but ... is. Second, `hasArg` never generates an error if given a name as an argument, whereas `missing(x)` generates an error if `x` is not a formal argument.

**Value**

Always TRUE or FALSE as described above.

**See Also**

[missing](#)

**Examples**

```
ftest <- function(x1, ...) c(hasArg(x1), hasArg("y2"))

ftest(1) ## c(TRUE, FALSE)
ftest(1, 2) ## c(TRUE, FALSE)
ftest(y2 = 2) ## c(FALSE, TRUE)
ftest(y = 2) ## c(FALSE, FALSE) (no partial matching)
ftest(y2 = 2, x = 1) ## c(TRUE, TRUE) partial match x1
```

---

implicitGeneric

*Manage Implicit Versions of Generic Functions*

---

**Description**

Create or access implicit generic functions, used to enforce consistent generic versions of functions that are not currently generic. Function `implicitGeneric()` returns the implicit generic version, `setGenericImplicit()` turns a generic implicit, `prohibitGeneric()` prevents your function from being made generic, and `registerImplicitGenerics()` saves a set of implicit generic definitions in the cached table of the current session.

**Usage**

```
implicitGeneric(name, where, generic)
setGenericImplicit(name, where, restore = TRUE)
prohibitGeneric(name, where)
registerImplicitGenerics(what, where)
```

**Arguments**

|                      |                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>    | Character string name of the function.                                                                                                                                                           |
| <code>where</code>   | Package or environment in which to register the implicit generics. When using the functions from the top level of your own package source, this argument can usually be omitted (and should be). |
| <code>generic</code> | Optionally, the generic function definition to be cached, but usually omitted. See Details section.                                                                                              |
| <code>restore</code> | Should the non-generic version of the function be restored after the current.                                                                                                                    |
| <code>what</code>    | For <code>registerImplicitGenerics()</code> , Optional table of the implicit generics to register, but nearly always omitted. See Details section.                                               |

## Details

Multiple packages may define methods for the same function, using the version of a function stored in one package. All these methods should be marshaled and dispatched consistently when a user calls the function. For consistency, the generic version of the function must have a unique definition (the same arguments allowed in methods signatures, the same values for optional slots such as the value class, and the same standard or non-standard definition of the function itself).

If the original function is already an S4 generic, there is no problem. The implicit generic mechanism enforces consistency when the version in the package owning the function is *not* generic. If a call to `setGeneric()` attempts to turn a function in another package into a generic, the mechanism compares the proposed new generic function to the implicit generic version of that function. If the two agree, all is well. If not, and if the function belongs to another package, then the new generic will not be associated with that package. Instead, a warning is issued and a separate generic function is created, with its package slot set to the current package, not the one that owns the non-generic version of the function. The effect is that the new package can still define methods for this function, but it will not share the methods in other packages, since it is forcing a different definition of the generic function.

The right way to proceed in nearly all cases is to call `setGeneric("foo")`, giving *only* the name of the function; this will automatically use the implicit generic version. If you don't like that version, the best solution is to convince the owner of the other package to agree with you and to insert code to define the non-default properties of the function (even if the owner does not want `foo()` to be a generic by default).

For any function, the implicit generic form is a standard generic in which all formal arguments, except for . . . , are allowed in the signature of methods. If that is the suitable generic for a function, no action is needed. If not, the best mechanism is to set up the generic in the code of the package owning the function, and to then call `setGenericImplicit()` to record the implicit generic and restore the non-generic version. See the example.

Note that the package can define methods for the implicit generic as well; when the implicit generic is made a real generic, those methods will be included.

Other than predefining methods, the usual reason for having a non-default implicit generic is to provide a non-default signature, and the usual reason for *that* is to allow lazy evaluation of some arguments. See the example. All arguments in the signature of a generic function must be evaluated at the time the function needs to select a method. (But those arguments can be missing, with or without a default expression being defined; you can always examine `missing(x)` even for arguments in the signature.)

If you want to completely prohibit anyone from turning your function into a generic, call `prohibitGeneric()`.

## Value

Function `implicitGeneric()` returns the implicit generic definition (and caches that definition the first time if it has to construct it).

The other functions exist for their side effect and return nothing useful.

[setGeneric](#)

## Examples

```
How we would make the function \link{with}() into a generic:
```

```
Since the second argument, expr is used literally, we want
with() to only have "data" in the signature.

Note that methods-internal code now has already extended with()
to do the equivalent of the following
Not run:
setGeneric("with", signature = "data")
Now we could predefine methods for "with" if we wanted to.

When ready, we store the generic as implicit, and restore the original
setGenericImplicit("with")

(This example would only work if we "owned" function with(),
but it is in base.)
End(Not run)

implicitGeneric("with")
```

---

inheritedSlotNames      *Names of Slots Inherited From a Super Class*

---

## Description

For a class (or class definition, see [getClass](#) and the description of class [classRepresentation](#)), give the names which are inherited from “above”, i.e., super classes, rather than by this class’ definition itself.

## Usage

```
inheritedSlotNames(Class, where = topenv(parent.frame()))
```

## Arguments

|       |                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------|
| Class | character string or <a href="#">classRepresentation</a> , i.e., resulting from <a href="#">getClass</a> . |
| where | environment, to be passed further to <a href="#">isClass</a> and <a href="#">getClass</a> .               |

## Value

character vector of slot names, or **NULL**.

## See Also

[slotNames](#), [slot](#), [setClass](#), etc.

## Examples

```
.srch <- search()
library(stats4)
inheritedSlotNames("mle")
```

```
Not run:
```

```

if(require("Matrix")) {
 print(inheritedSlotNames("Matrix")) # NULL
 ## whereas
 print(inheritedSlotNames("sparseMatrix")) # --> Dim & Dimnames
 ## i.e. inherited from "Matrix" class

 print(cl <- getClass("dgCMatrix")) # six slots, etc

 print(inheritedSlotNames(cl)) # *all* six slots are inherited
}

detach package we've attached above:
for(n in rev(which(is.na(match(search(), .srch))))) {
 try(detach(pos = n))

End(Not run)

```

## Description

The arguments to function `new` to create an object from a particular class can be interpreted specially for that class, by the definition of a method for function `initialize` for the class. This documentation describes some existing methods, and also outlines how to write new ones.

## Methods

`signature(.Object = "ANY")` The default method for `initialize` takes either named or unnamed arguments. Argument names must be the names of slots in this class definition, and the corresponding arguments must be valid objects for the slot (that is, have the same class as specified for the slot, or some superclass of that class). If the object comes from a superclass, it is not coerced strictly, so normally it will retain its current class (specifically, `as(object, Class, strict = FALSE)`).

Unnamed arguments must be objects of this class, of one of its superclasses, or one of its subclasses (from the class, from a class this class extends, or from a class that extends this class). If the object is from a superclass, this normally defines some of the slots in the object. If the object is from a subclass, the new object is that argument, coerced to the current class.

Unnamed arguments are processed first, in the order they appear. Then named arguments are processed. Therefore, explicit values for slots always override any values inferred from superclass or subclass arguments.

`signature(.Object = "traceable")` Objects of a class that extends `traceable` are used to implement debug tracing (see class `traceable` and `trace`).

The `initialize` method for these classes takes special arguments `def`, `tracer`, `exit`, `at`, `print`. The first of these is the object to use as the original definition (e.g., a function). The others correspond to the arguments to `trace`.

`signature(.Object = "environment"), signature(.Object = ".environment")` The `initialize` method for environments takes a named list of objects to be used to initialize the environment. Subclasses of `"environment"` inherit an `initialize` method through `".environment"`, which has the additional effect of allocating a new environment. If you

define your own method for such a subclass, be sure either to call the existing method via `callNextMethod` or allocate an environment in your method, since environments are references and are not duplicated automatically.

`signature(.Object = "signature")` This is a method for internal use only. It takes an optional `functionDef` argument to provide a generic function with a `signature` slot to define the argument names. See [Methods](#) for details.

## Writing Initialization Methods

Initialization methods provide a general mechanism corresponding to generator functions in other languages.

The arguments to `initialize` are `.Object` and .... Nearly always, `initialize` is called from new, not directly. The `.Object` argument is then the prototype object from the class.

Two techniques are often appropriate for `initialize` methods: special argument names and `callNextMethod`.

You may want argument names that are more natural to your users than the (default) slot names. These will be the formal arguments to your method definition, in addition to `.Object` (always) and ... (optionally). For example, the method for class "traceable" documented above would be created by a call to `setMethod` of the form:

```
setMethod("initialize", "traceable",
 function(.Object, def, tracer, exit, at, print) ...
)
```

In this example, no other arguments are meaningful, and the resulting method will throw an error if other names are supplied.

When your new class extends another class, you may want to call the `initialize` method for this superclass (either a special method or the default). For example, suppose you want to define a method for your class, with special argument `x`, but you also want users to be able to set slots specifically. If you want `x` to override the slot information, the beginning of your method definition might look something like this:

```
function(.Object, x, ...) {
 Object <- callNextMethod(.Object, ...)
 if(!missing(x)) { # do something with x
```

You could also choose to have the inherited method override, by first interpreting `x`, and then calling the next method.

## Description

Functions to test inheritance relationships between an object and a class (`is`) or between two classes (`extends`), and to establish such relationships (`setIs`, an explicit alternative to the `contains=` argument to `setClass`).

## Usage

```
is(object, class2)

extends(class1, class2, maybe = TRUE, fullInfo = FALSE)

setIs(class1, class2, test=NULL, coerce=NULL, replace=NULL,
 by = character(), where = topenv(parent.frame()), classDef =,
 extensionObject = NULL, doComplete = TRUE)
```

## Arguments

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object          | any R object.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| class1, class2  | the names of the classes between which is relations are to be examined defined, or (more efficiently) the class definition objects for the classes.                                                                                                                                                                                                                                                                                   |
| maybe, fullInfo | In a call to extends, maybe is the value returned if a relation is conditional. In a call with class2 missing, fullInfo is a flag, which if TRUE causes a list of objects of class classExtension to be returned, rather than just the names of the classes.                                                                                                                                                                          |
| coerce, replace | In a call to setIs, functions optionally supplied to coerce the object to class2, and to alter the object so that is(object, class2) is identical to value. See the details section below.                                                                                                                                                                                                                                            |
| test            | In a call to setIs, a <i>conditional</i> relationship is defined by supplying this function. Conditional relations are discouraged and are not included in selecting methods. See the details section below.                                                                                                                                                                                                                          |
|                 | The remaining arguments are for internal use and/or usually omitted.                                                                                                                                                                                                                                                                                                                                                                  |
| extensionObject | alternative to the test, coerce, replace, by arguments; an object from class SClassExtension describing the relation. (Used in internal calls.)                                                                                                                                                                                                                                                                                       |
| doComplete      | when TRUE, the class definitions will be augmented with indirect relations as well. (Used in internal calls.)                                                                                                                                                                                                                                                                                                                         |
| by              | In a call to setIs, the name of an intermediary class. Coercion will proceed by first coercing to this class and from there to the target class. (The intermediate coercions have to be valid.)                                                                                                                                                                                                                                       |
| where           | In a call to setIs, where to store the metadata defining the relationship. Default is the global environment for calls from the top level of the session or a source file evaluated there. When the call occurs in the top level of a file in the source of a package, the default will be the namespace or environment of the package. Other uses are tricky and not usually a good idea, unless you really know what you are doing. |
| classDef        | Optional class definition for class , required internally when setIs is called during the initial definition of the class by a call to <a href="#">setClass</a> . Don't use this argument, unless you really know why you're doing so.                                                                                                                                                                                                |

## Summary of Functions

**is:** With two arguments, tests whether object can be treated as from class2.

With one argument, returns all the super-classes of this object's class.

**extends:** Does the first class extend the second class? The call returns `maybe` if the extension includes a test.

When called with one argument, the value is a vector of the superclasses of `class1`. If argument `fullInfo` is `TRUE`, the call returns a named list of objects of class `SClassExtension`; otherwise, just the names of the superclasses.

**setIs:** Defines `class1` to be an extension (subclass) of `class2`. If `class2` is an existing virtual class, such as a class union, then only the two classes need to be supplied in the call, if the implied inherited methods work for `class1`. See the details section below.

Alternatively, arguments `coerce` and `replace` should be supplied, defining methods to coerce to the superclass and to replace the part corresponding to the superclass. As discussed in the details and other sections below, this form is often less recommended than the corresponding call to `setAs`, to which it is an alternative.

Argument `test` allows conditional inheritance, in which the `is()` result is tested for each object rather than being determined by the class definition. This form is discouraged when it can be avoided; in particular, note that conditional inheritance is *not* used to select methods for dispatch.

## Details

Arranging for a class to inherit from another class is a key tool in programming. In R, there are three basic techniques, the first two providing what is called “simple” inheritance, the preferred form:

1. By the `contains=` argument in a call to `setClass`. This is and should be the most common mechanism. It arranges that the new class contains all the structure of the existing class, and in particular all the slots with the same class specified. The resulting class extension is defined to be `simple`, with important implications for method definition (see the section on this topic below).
2. Making `class1` a subclass of a virtual class either by a call to `setClassUnion` to make the subclass a member of a new class union, or by a call to `setIs` to add a class to an existing class union or as a new subclass of an existing virtual class. In either case, the implication should be that methods defined for the class union or other superclass all work correctly for the subclass. This may depend on some similarity in the structure of the subclasses or simply indicate that the superclass methods are defined in terms of generic functions that apply to all the subclasses. These relationships are also generally simple.
3. Supplying `coerce` and `replace` arguments to `setAs`. R allows arbitrary inheritance relationships, using the same mechanism for defining coerce methods by a call to `setAs`. The difference between the two is simply that `setAs` will require a call to `as` for a conversion to take place, whereas after the call to `setIs`, objects will be automatically converted to the superclass.

The automatic feature is the dangerous part, mainly because it results in the subclass potentially inheriting methods that do not work. See the section on inheritance below. If the two classes involved do not actually inherit a large collection of methods, as in the first example below, the danger may be relatively slight.

If the superclass inherits methods where the subclass has only a default or remotely inherited method, problems are more likely. In this case, a general recommendation is to use the `setAs` mechanism instead, unless there is a strong counter reason. Otherwise, be prepared to override some of the methods inherited.

With this caution given, the rest of this section describes what happens when `coerce=` and `replace=` arguments are supplied to `setIs`.

The `coerce` and `replace` arguments are functions that define how to coerce a `class1` object to `class2`, and how to replace the part of the subclass object that corresponds to `class2`. The first of these is a function of one argument which should be `from`, and the second of two arguments (`from`, `value`). For details, see the section on coerce functions below.

When `by` is specified, the coerce process first coerces to this class and then to `class2`. It's unlikely you would use the `by` argument directly, but it is used in defining cached information about classes.

The value returned (invisibly) by `setIs` is the revised class definition of `class1`.

### Coerce, replace, and test functions

The `coerce` argument is a function that turns a `class1` object into a `class2` object. The `replace` argument is a function of two arguments that modifies a `class1` object (the first argument) to replace the part of it that corresponds to `class2` (supplied as `value`, the second argument). It then returns the modified object as the value of the call. In other words, it acts as a replacement method to implement the expression `as(object, class2) <- value`.

The easiest way to think of the `coerce` and `replace` functions is by thinking of the case that `class1` contains `class2` in the usual sense, by including the slots of the second class. (To repeat, in this situation you would not call `setIs`, but the analogy shows what happens when you do.)

The `coerce` function in this case would just make a `class2` object by extracting the corresponding slots from the `class1` object. The `replace` function would replace in the `class1` object the slots corresponding to `class2`, and return the modified object as its value.

For additional discussion of these functions, see the documentation of the `setAs` function. (Unfortunately, argument `def` to that function corresponds to argument `coerce` here.)

The inheritance relationship can also be conditional, if a function is supplied as the `test` argument. This should be a function of one argument that returns TRUE or FALSE according to whether the object supplied satisfies the relation `is(object, class2)`. Conditional relations between classes are discouraged in general because they require a per-object calculation to determine their validity. They cannot be applied as efficiently as ordinary relations and tend to make the code that uses them harder to interpret. *NOTE: conditional inheritance is not used to dispatch methods.* Methods for conditional superclasses will not be inherited. Instead, a method for the subclass should be defined that tests the conditional relationship.

### Inherited methods

A method written for a particular signature (classes matched to one or more formal arguments to the function) naturally assumes that the objects corresponding to the arguments can be treated as coming from the corresponding classes. The objects will have all the slots and available methods for the classes.

The code that selects and dispatches the methods ensures that this assumption is correct. If the inheritance was “simple”, that is, defined by one or more uses of the `contains=` argument in a call to `setClass`, no extra work is generally needed. Classes are inherited from the superclass, with the same definition.

When inheritance is defined by a general call to `setIs`, extra computations are required. This form of inheritance implies that the subclass does *not* just contain the slots of the superclass, but instead requires the explicit call to the `coerce` and/or `replace` method. To ensure correct computation, the inherited method is supplemented by calls to `as` before the body of the method is evaluated.

The calls to `as` generated in this case have the argument `strict = FALSE`, meaning that extra information can be left in the converted object, so long as it has all the appropriate slots. (It's this option that allows simple subclass objects to be used without any change.) When you are writing your `coerce` method, you may want to take advantage of that option.

Methods inherited through non-simple extensions can result in ambiguities or unexpected selections. If `class2` is a specialized class with just a few applicable methods, creating the inheritance relation may have little effect on the behavior of `class1`. But if `class2` is a class with many methods, you may find that you now inherit some undesirable methods for `class1`, in some cases, fail to inherit expected methods. In the second example below, the non-simple inheritance from class "factor" might be assumed to inherit S3 methods via that class. But the S3 class is ambiguous, and in fact is "character" rather than "factor".

For some generic functions, methods inherited by non-simple extensions are either known to be invalid or sufficiently likely to be so that the generic function has been defined to exclude such inheritance. For example `initialize` methods must return an object of the target class; this is straightforward if the extension is simple, because no change is made to the argument object, but is essentially impossible. For this reason, the generic function insists on only simple extensions for inheritance. See the `simpleInheritanceOnly` argument to `setGeneric` for the mechanism. You can use this mechanism when defining new generic functions.

If you get into problems with functions that do allow non-simple inheritance, there are two basic choices. Either back off from the `setIs` call and settle for explicit coercing defined by a call to `setAs`; or, define explicit methods involving `class1` to override the bad inherited methods. The first choice is the safer, when there are serious problems.

## See Also

`inherits` is nearly always equivalent to `is`, both for S4 and non-S4 objects, and is somewhat faster. The non-equivalence applies to classes that have conditional superclasses, with a non-trivial `test=` in the relation (not common and discouraged): for these, `is` tests for the relation but `inherits` by definition ignores conditional inheritance for S4 objects.

`selectSuperClasses(c1)` has similar semantics as `extends(c1)`, typically returning subsets of the latter.

## Examples

```
Two examples of setIs() with coerce= and replace= arguments
The first one works fairly well, because neither class has many
inherited methods do be disturbed by the new inheritance

The second example does NOT work well, because the new superclass,
"factor", causes methods to be inherited that should not be.

First example:
a class definition (see \link{setClass} for class "track")
setClass("trackCurve", contains = "track",
 representation(smooth = "numeric"))
A class similar to "trackCurve", but with different structure
allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
 representation(x="numeric", y="matrix", smooth="matrix"),
 prototype = structure(list(), x=numeric(), y=matrix(0,0,0),
```

```

smooth= matrix(0,0,0)))
Automatically convert an object from class "trackCurve" into
"trackMultiCurve", by making the y, smooth slots into 1-column matrices
setIs("trackCurve",
 "trackMultiCurve",
 coerce = function(obj) {
 new("trackMultiCurve",
 x = obj@x,
 y = as.matrix(obj@y),
 smooth = as.matrix(obj@smooth))
 },
 replace = function(obj, value) {
 obj@y <- as.matrix(value@y)
 obj@x <- value@x
 obj@smooth <- as.matrix(value@smooth)
 obj})
}

Second Example:
A class that adds a slot to "character"
setClass("stringsDated", contains = "character",
 representation(stamp="POSIXt"))

Convert automatically to a factor by explicit coerce
setIs("stringsDated", "factor",
 coerce = function(from) factor(from@Data),
 replace= function(from, value) {
 from@Data <- as.character(value); from })

ll <- sample(letters, 10, replace = TRUE)
ld <- new("stringsDated", ll, stamp = Sys.time())

levels(as(ld, "factor"))
levels(ld) # will be NULL--see comment in section on inheritance above.

In contrast, a class that simply extends "factor"
has no such ambiguities
setClass("factorDated", contains = "factor",
 representation(stamp="POSIXt"))
fd <- new("factorDated", factor(ll), stamp = Sys.time())
identical(levels(fd), levels(as(fd, "factor")))

```

**isSealedMethod***Check for a Sealed Method or Class*

## Description

These functions check for either a method or a class that has been *sealed* when it was defined, and which therefore cannot be re-defined.

## Usage

```
isSealedMethod(f, signature, fdef, where)
isSealedClass(Class, where)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>         | The quoted name of the generic function.                                                                                                                                                                                                                                               |
| <code>signature</code> | The class names in the method's signature, as they would be supplied to <a href="#">setMethod</a> .                                                                                                                                                                                    |
| <code>fdef</code>      | Optional, and usually omitted: the generic function definition for <code>f</code> .                                                                                                                                                                                                    |
| <code>Class</code>     | The quoted name of the class.                                                                                                                                                                                                                                                          |
| <code>where</code>     | where to search for the method or class definition. By default, searches from the top environment of the call to <code>isSealedMethod</code> or <code>isSealedClass</code> , typically the global environment or the namespace of a package containing a call to one of the functions. |

## Details

In the R implementation of classes and methods, it is possible to seal the definition of either a class or a method. The basic classes (numeric and other types of vectors, matrix and array data) are sealed. So also are the methods for the primitive functions on those data types. The effect is that programmers cannot re-define the meaning of these basic data types and computations. More precisely, for primitive functions that depend on only one data argument, methods cannot be specified for basic classes. For functions (such as the arithmetic operators) that depend on two arguments, methods can be specified if *one* of those arguments is a basic class, but not if both are.

Programmers can seal other class and method definitions by using the `sealed` argument to [setClass](#) or [setMethod](#).

## Value

The functions return FALSE if the method or class is not sealed (including the case that it is not defined); TRUE if it is.

## References

- Chambers, John M. (2008) *Software for Data Analysis: Programming with R* Springer. (For the R version.)  
 Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

## Examples

```
these are both TRUE
isSealedMethod("+", c("numeric", "character"))
isSealedClass("matrix")

setClass("track",
 representation(x="numeric", y="numeric"))
but this is FALSE
isSealedClass("track")
and so is this
isSealedClass("A Name for an undefined Class")
and so are these, because only one of the two arguments is basic
isSealedMethod("+", c("track", "numeric"))
isSealedMethod("+", c("numeric", "track"))
```

**language-class***Classes to Represent Unevaluated Language Objects***Description**

The virtual class "language" and the specific classes that extend it represent unevaluated objects, as produced for example by the parser or by functions such as [quote](#).

**Usage**

```
each of these classes corresponds to an unevaluated object
in the S language.
The class name can appear in method signatures,
and in a few other contexts (such as some calls to as()).

"("
"<="
"call"
"for"
"if"
"repeat"
"while"
"name"
"{"

Each of the classes above extends the virtual class
"language"
```

**Objects from the Class**

"language" is a virtual class; no objects may be created from it.

Objects from the other classes can be generated by a call to new(Class, ...), where Class is the quoted class name, and the ... arguments are either empty or a *single* object that is from this class (or an extension).

**Methods**

**coerce** signature(from = "ANY", to = "call"). A method exists for as(object, "call"), calling as.call().

**LinearMethodsList-class***Class "LinearMethodsList"***Description**

A version of methods lists that has been ‘linearized’ for producing summary information. The actual objects from class "MethodsList" used for method dispatch are defined recursively over the arguments involved.

## Objects from the Class

The function `linearizeMlist` converts an ordinary methods list object into the linearized form.

### Slots

`methods`: Object of class "list", the method definitions.

`arguments`: Object of class "list", the corresponding formal arguments, namely as many of the arguments in the signature of the generic function as are active in the relevant method table.

`classes`: Object of class "list", the corresponding classes in the signatures.

`generic`: Object of class "genericFunction"; the generic function to which the methods correspond.

### Future Note

The current version of `linearizeMlist` does not take advantage of the `MethodDefinition` class, and therefore does more work for less effect than it could. In particular, we may move to redefine both the function and the class to take advantage of the stored signatures. Don't write code depending precisely on the present form, although all the current information will be obtainable in the future.

### See Also

Function `linearizeMlist` for the computation, and class `MethodsList` for the original, recursive form.

---

LocalReferenceClasses *Localized Objects based on Reference Classes*

---

### Description

Local reference classes are modified `ReferenceClasses` that isolate the objects to the local frame. Therefore, they do *not* propagate changes back to the calling environment. At the same time, they use the reference field semantics locally, avoiding the automatic duplication applied to standard R objects.

The current implementation has no special construction. To create a local reference class, call `setRefClass()` with a `contains=` argument that includes "localRefClass". See the example below.

Local reference classes operate essentially as do regular, functional classes in R; that is, changes are made by assignment and take place in the local frame. The essential difference is that replacement operations (like the change to the `twiddle` field in the example) do not cause duplication of the entire object, as would be the case for a formal class or for data with attributes or in a named list. The purpose is to allow large objects in some fields that are not changed along with potentially frequent changes to other fields, but without copying the large fields.

### Usage

```
setRefClass(Class, fields = , contains = c("localRefClass", ...),
 methods = , where = , ...)
```

## Details

Localization of objects is only partially automated in the current implementation. Replacement expressions using the \$<- operator are safe.

However, if reference methods for the class themselves modify fields, using <<-, for example, then one must ensure that the object is local to the relevant frame before any such method is called. Otherwise, standard reference class behavior still prevails.

There are two ways to ensure locality. The direct way is to invoke the special method x\$ensureLocal() on the object. The other way is to modify a field explicitly by x\$field <- ... It's only necessary that one or the other of these happens once for each object, in order to trigger the shallow copy that provides locality for the references. In the example below, we show both mechanisms.

However it's done, localization must occur *before* any methods make changes. (Eventually, some use of code tools should at least largely automate this process, although it may be difficult to guarantee success under arbitrary circumstances.)

## Author(s)

John Chambers

## Examples

```
class "myIter" has a BigData field for the real (big) data
and a "twiddle" field for some parameters that it twiddles
(for some reason)

myIter <- setRefClass("myIter", contains = "localRefClass",
 fields = list(BigData = "numeric", twiddle = "numeric"))

tw <- rnorm(3)
x1 <- myIter(BigData = rnorm(1000), twiddle = tw) # OK, not REALLY big

twiddler <- function(x, n) {
 x$ensureLocal() # see the Details. Not really needed in this example
 for(i in seq(length = n)) {
 x$twiddle <- x$twiddle + rnorm(length(x$twiddle))
 ## then do something
 ## Snooping in gdb, etc will show that x$BigData is not copied
 }
 return(x)
}

x2 <- twiddler(x1, 10)

stopifnot(identical(x1$twiddle, tw), !identical(x1$twiddle, x2$twiddle))
```

## Description

Constructs an object of class `classRepresentation` to describe a particular class. Mostly a utility function, but you can call it to create a class definition without assigning it, as `setClass` would do.

## Usage

```
makeClassRepresentation(name, slots=list(), superClasses=character(),
 prototype=NULL, package, validity, access,
 version, sealed, virtual=NA, where)
```

## Arguments

|                           |                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>         | character string name for the class                                                                                                                                          |
| <code>slots</code>        | named list of slot classes as would be supplied to <code>setClass</code> , but <i>without</i> the unnamed arguments for <code>superClasses</code> if any.                    |
| <code>superClasses</code> | what classes does this class extend                                                                                                                                          |
| <code>prototype</code>    | an object providing the default data for the class, e.g, the result of a call to <code>prototype</code> .                                                                    |
| <code>package</code>      | The character string name for the package in which the class will be stored; see <code>getPackageName</code> .                                                               |
| <code>validity</code>     | Optional validity method. See <code>validObject</code> , and the discussion of validity methods in the reference.                                                            |
| <code>access</code>       | Access information. Not currently used.                                                                                                                                      |
| <code>version</code>      | Optional version key for version control. Currently generated, but not used.                                                                                                 |
| <code>sealed</code>       | Is the class sealed? See <code>setClass</code> .                                                                                                                             |
| <code>virtual</code>      | Is this known to be a virtual class?                                                                                                                                         |
| <code>where</code>        | The environment from which to look for class definitions needed (e.g., for slots or superclasses). See the discussion of this argument under <code>GenericFunctions</code> . |

## See Also

`setClass`

**method.skeleton** *Create a Skeleton File for a New Method*

## Description

This function writes a source file containing a call to [setMethod](#) to define a method for the generic function and signature supplied. By default the method definition is in line in the call, but can be made an external (previously assigned) function.

## Usage

```
method.skeleton(generic, signature, file, external = FALSE, where)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| generic   | the character string name of the generic function, or the generic function itself. In the first case, the function need not currently be a generic, as it would not for the resulting call to <a href="#">setMethod</a> .                                                                                                                                                                                |
| signature | the method signature, as it would be given to <a href="#">setMethod</a>                                                                                                                                                                                                                                                                                                                                  |
| file      | a character string name for the output file, or a writable connection. By default the generic function name and the classes in the signature are concatenated, with separating underscore characters. The file name should normally end in ".R".<br>To write multiple method skeletons to one file, open the file connection first and then pass it to <code>method.skeleton()</code> in multiple calls. |
| external  | flag to control whether the function definition for the method should be a separate external object assigned in the source file, or included in line in the call to <a href="#">setMethod</a> . If supplied as a character string, this will be used as the name for the external function; by default the name concatenates the generic and signature names, with separating underscores.               |
| where     | The environment in which to look for the function; by default, the top-level environment of the call to <code>method.skeleton</code> .                                                                                                                                                                                                                                                                   |

## Value

The `file` argument, invisibly, but the function is used for its side effect.

## See Also

[setMethod](#), [package.skeleton](#)

## Examples

```
setClass("track", representation(x ="numeric", y="numeric"))
method.skeleton("show", "track") ## writes show_track.R
method.skeleton("Ops", c("track", "track")) ## writes "Ops_track_track.R"

write multiple method skeletons to one file
con <- file("./Math_track.R", "w")
method.skeleton("Math", "track", con)
method.skeleton("exp", "track", con)
method.skeleton("log", "track", con)
```

```
close(con)
```

---

**MethodDefinition-class***Classes to Represent Method Definitions*

---

**Description**

These classes extend the basic class "function" when functions are to be stored and used as method definitions.

**Details**

Method definition objects are functions with additional information defining how the function is being used as a method. The target slot is the class signature for which the method will be dispatched, and the defined slot the signature for which the method was originally specified (that is, the one that appeared in some call to [setMethod](#)).

**Objects from the Class**

The action of setting a method by a call to [setMethod](#) creates an object of this class. It's unwise to create them directly.

The class "SealedMethodDefinition" is created by a call to [setMethod](#) with argument sealed = TRUE. It has the same representation as "MethodDefinition".

**Slots**

.Data: Object of class "function"; the data part of the definition.

target: Object of class "signature"; the signature for which the method was wanted.

defined: Object of class "signature"; the signature for which a method was found. If the method was inherited, this will not be identical to target.

generic: Object of class "character"; the function for which the method was created.

**Extends**

Class "function", from data part.

Class "PossibleMethod", directly.

Class "OptionalMethods", by class "function".

**See Also**

class [MethodsList](#) for the objects defining sets of methods associated with a particular generic function. The individual method definitions stored in these objects are from class [MethodDefinition](#), or an extension. Class [MethodWithNext](#) for an extension used by [callNextMethod](#).

## Description

This documentation section covers some general topics on how methods work and how the **methods** package interacts with the rest of R. The information is usually not needed to get started with methods and classes, but may be helpful for moderately ambitious projects, or when something doesn't work as expected.

The section "How Methods Work" describes the underlying mechanism; "S3 Methods and Generic Functions" gives the rules applied when S4 classes and methods interact with older S3 methods; "Method Selection and Dispatch" provides more details on how class definitions determine which methods are used; "Generic Functions" discusses generic functions as objects. For additional information specifically about class definitions, see [Classes](#).

### How Methods Work

A generic function has associated with it a collection of other functions (the methods), all of which have the same formal arguments as the generic. See the "Generic Functions" section below for more on generic functions themselves.

Each R package will include methods metadata objects corresponding to each generic function for which methods have been defined in that package. When the package is loaded into an R session, the methods for each generic function are *cached*, that is, stored in the environment of the generic function along with the methods from previously loaded packages. This merged table of methods is used to dispatch or select methods from the generic, using class inheritance and possibly group generic functions (see [GroupGenericFunctions](#)) to find an applicable method. See the "Method Selection and Dispatch" section below. The caching computations ensure that only one version of each generic function is visible globally; although different attached packages may contain a copy of the generic function, these behave identically with respect to method selection. In contrast, it is possible for the same function name to refer to more than one generic function, when these have different package slots. In the latter case, R considers the functions unrelated: A generic function is defined by the combination of name and package. See the "Generic Functions" section below.

The methods for a generic are stored according to the corresponding signature in the call to [setMethod](#) that defined the method. The signature associates one class name with each of a subset of the formal arguments to the generic function. Which formal arguments are available, and the order in which they appear, are determined by the "signature" slot of the generic function itself. By default, the signature of the generic consists of all the formal arguments except ..., in the order they appear in the function definition.

Trailing arguments in the signature of the generic will be *inactive* if no method has yet been specified that included those arguments in its signature. Inactive arguments are not needed or used in labeling the cached methods. (The distinction does not change which methods are dispatched, but ignoring inactive arguments improves the efficiency of dispatch.)

All arguments in the signature of the generic function will be evaluated when the function is called, rather than using the traditional lazy evaluation rules of S. Therefore, it's important to *exclude* from the signature any arguments that need to be dealt with symbolically (such as the first argument to function [substitute](#)). Note that only actual arguments are evaluated, not default expressions. A missing argument enters into the method selection as class "missing".

The cached methods are stored in an environment object. The names used for assignment are a concatenation of the class names for the active arguments in the method signature.

## Methods for S3 Generic Functions

S4 methods may be wanted for functions that also have S3 methods, corresponding to classes for the first formal argument of an S3 generic function—either a regular R function in which there is a call to the S3 dispatch function, [UseMethod](#), or one of a fixed set of primitive functions, which are not true functions but go directly to C code. In either case S3 method dispatch looks at the class of the first argument or the class of either argument in a call to one of the primitive binary operators. S3 methods are ordinary functions with the same arguments as the generic function (for primitives the formal arguments are not actually part of the object, but are simulated when the object is printed or viewed by [args\(\)](#)). The “signature” of an S3 method is identified by the name to which the method is assigned, composed of the name of the generic function, followed by “.”, followed by the name of the class. For details, see [S3Methods](#).

To implement a method for one of these functions corresponding to S4 classes, there are two possibilities: either an S4 method or an S3 method with the S4 class name. The S3 method is only possible if the intended signature has the first argument and nothing else. In this case, the recommended approach is to define the S3 method and also supply the identical function as the definition of the S4 method. If the S3 generic function was `f3(x, ...)` and the S4 class for the new method was “`myClass`”:

```
f3.myClass <- function(x, ...) { }
setMethod("f3", "myClass", f3.myClass)
```

The reasons for defining both S3 and S4 methods are as follows:

1. An S4 method alone will not be seen if the S3 generic function is called directly. However, primitive functions and operators are exceptions: The internal C code will look for S4 methods if and only if the object is an S4 object. In the examples, the method for `[` for class “`myFrame`” will always be called for objects of this class.  
For the same reason, an S4 method defined for an S3 class will not be called from internal code for a non-S4 object. (See the example for function `Math` and class “`data.frame`” in the examples.)
2. An S3 method alone will not be called if there is *any* eligible non-default S4 method. (See the example for function `f3` and class “`classA`” in the examples.)

Details of the selection computations are given below.

When an S4 method is defined for an existing function that is not an S4 generic function (whether or not the existing function is an S3 generic), an S4 generic function will be created corresponding to the existing function and the package in which it is found (more precisely, according to the implicit generic function either specified or inferred from the ordinary function; see [implicitGeneric](#)). A message is printed after the initial call to [setMethod](#); this is not an error, just a reminder that you have created the generic. Creating the generic explicitly by the call

```
setGeneric("f3")
```

avoids the message, but has the same effect. The existing function becomes the default method for the S4 generic function. Primitive functions work the same way, but the S4 generic function is not explicitly created (as discussed below).

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible. S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered by a call to [setOldClass](#), with that call specifying the correct S3 inheritance pattern. S4 classes can be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the contents of [extends\(class\(x\)\)](#) as the equivalent of the S3 inheritance (the inheritance is cached after the first call).

An existing S3 method may not behave as desired for an S4 subclass, in which case utilities such as [asS3](#) and [S3Part](#) may be useful. If the S3 method fails on the S4 object, [asS3\(x\)](#) may be

passed instead; if the object returned by the S3 method needs to be incorporated in the S4 object, the replacement function for `S3Part` may be useful, as in the method for class "myFrame" in the examples.

Here are details explaining the reasons for defining both S3 and S4 methods. Calls still accessing the S3 generic function directly will not see S4 methods, except in the case of primitive functions. This means that calls to the generic function from namespaces that import the S3 generic but not the S4 version will only see S3 methods. On the other hand, S3 methods will only be selected from the S4 generic function as part of its default ("ANY") method. If there are inherited S4 non-default methods, these will be chosen in preference to *any* S3 method.

S3 generic functions implemented as primitive functions (including binary operators) are an exception to recognizing only S3 methods. These functions dispatch both S4 and S3 methods from the internal C code. There is no explicit generic function, either S3 or S4. The internal code looks for S4 methods if the first argument, or either of the arguments in the case of a binary operator, is an S4 object. If no S4 method is found, a search is made for an S3 method.

S4 methods can be defined for an S3 generic function and an S3 class, but if the function is a primitive, such methods will not be selected if the object in question is not an S4 object. In the examples below, for instance, an S4 method for signature "data.frame" for function `f3()` would be called for the S3 object `df1`. A similar S4 method for primitive function `[` would be ignored for that object, but would be called for the S4 object `mydf1` that inherits from "data.frame". Defining both an S3 and S4 method removes this inconsistency.

### Method Selection and Dispatch: Details

When a call to a generic function is evaluated, a method is selected corresponding to the classes of the actual arguments in the signature. First, the cached methods table is searched for an exact match; that is, a method stored under the signature defined by the string value of `class(x)` for each non-missing argument, and "missing" for each missing argument. If no method is found directly for the actual arguments in a call to a generic function, an attempt is made to match the available methods to the arguments by using the superclass information about the actual classes.

Each class definition may include a list of one or more *superclasses* of the new class. The simplest and most common specification is by the `contains=` argument in the call to `setClass`. Each class named in this argument is a superclass of the new class. Two additional mechanisms for defining superclasses exist. A call to `setClassUnion` creates a union class that is a superclass of each of the members of the union. A call to `setIs` can create an inheritance relationship that is not the simple one of containing the superclass representation in the new class. Arguments `coerce` and `replace` supply methods to convert to the superclass and to replace the part corresponding to the superclass. (In addition, a `test=` argument allows conditional inheritance; conditional inheritance is not recommended and is not used in method selection.) All three mechanisms are treated equivalently for purposes of method selection: they define the *direct* superclasses of a particular class. For more details on the mechanisms, see [Classes](#).

The direct superclasses themselves may have superclasses, defined by any of the same mechanisms, and similarly through further generations. Putting all this information together produces the full list of superclasses for this class. The superclass list is included in the definition of the class that is cached during the R session. Each element of the list describes the nature of the relationship (see `SClassExtension` for details). Included in the element is a `distance` slot containing the path length for the relationship: 1 for direct superclasses (regardless of which mechanism defined them), then 2 for the direct superclasses of those classes, and so on. In addition, any class implicitly has class "ANY" as a superclass. The distance to "ANY" is treated as larger than the distance to any actual class. The special class "missing" corresponding to missing arguments has only "ANY" as a superclass, while "ANY" has no superclasses.

When a class definition is created or modified, the superclasses are ordered, first by a stable sort of the all superclasses by distance. If the set of superclasses has duplicates (that is, if some class is inherited through more than one relationship), these are removed, if possible, so that the list of superclasses is consistent with the superclasses of all direct superclasses. See the reference on inheritance for details.

The information about superclasses is summarized when a class definition is printed.

When a method is to be selected by inheritance, a search is made in the table for all methods directly corresponding to a combination of either the direct class or one of its superclasses, for each argument in the active signature. For an example, suppose there is only one argument in the signature and that the class of the corresponding object was "dgeMatrix" (from the recommended package `Matrix`). This class has two direct superclasses and through these 4 additional superclasses. Method selection finds all the methods in the table of directly specified methods labeled by one of these classes, or by "ANY".

When there are multiple arguments in the signature, each argument will generate a similar list of inherited classes. The possible matches are now all the combinations of classes from each argument (think of the function `outer` generating an array of all possible combinations). The search now finds all the methods matching any of this combination of classes. For each argument, the position in the list of superclasses of that argument's class defines which method or methods (if the same class appears more than once) match best. When there is only one argument, the best match is unambiguous. With more than one argument, there may be zero or one match that is among the best matches for *all* arguments.

If there is no best match, the selection is ambiguous and a message is printed noting which method was selected (the first method lexicographically in the ordering) and what other methods could have been selected. Since the ambiguity is usually nothing the end user could control, this is not a warning. Package authors should examine their package for possible ambiguous inheritance by calling `testInheritedMethods`.

When the inherited method has been selected, the selection is cached in the generic function so that future calls with the same class will not require repeating the search. Cached inherited selections are not themselves used in future inheritance searches, since that could result in invalid selections. If you want inheritance computations to be done again (for example, because a newly loaded package has a more direct method than one that has already been used in this session), call `resetGeneric`. Because classes and methods involving them tend to come from the same package, the current implementation does not reset all generics every time a new package is loaded.

Besides being initiated through calls to the generic function, method selection can be done explicitly by calling the function `selectMethod`.

Once a method has been selected, the evaluator creates a new context in which a call to the method is evaluated. The context is initialized with the arguments from the call to the generic function. These arguments are not rematched. All the arguments in the signature of the generic will have been evaluated (including any that are currently inactive); arguments that are not in the signature will obey the usual lazy evaluation rules of the language. If an argument was missing in the call, its default expression if any will *not* have been evaluated, since method dispatch always uses `class missing` for such arguments.

A call to a generic function therefore has two contexts: one for the function and a second for the method. The argument objects will be copied to the second context, but not any local objects created in a nonstandard generic function. The other important distinction is that the parent ("enclosing") environment of the second context is the environment of the method as a function, so that all R programming techniques using such environments apply to method definitions as ordinary functions.

For further discussion of method selection and dispatch, see the first reference.

## Generic Functions

In principle, a generic function could be any function that evaluates a call to `standardGeneric()`, the internal function that selects a method and evaluates a call to the selected method. In practice, generic functions are special objects that in addition to being from a subclass of class "function" also extend the class `genericFunction`. Such objects have slots to define information needed to deal with their methods. They also have specialized environments, containing the tables used in method selection.

The slots "generic" and "package" in the object are the character string names of the generic function itself and of the package from which the function is defined. As with classes, generic functions are uniquely defined in R by the combination of the two names. There can be generic functions of the same name associated with different packages (although inevitably keeping such functions cleanly distinguished is not always easy). On the other hand, R will enforce that only one definition of a generic function can be associated with a particular combination of function and package name, in the current session or other active version of R.

Tables of methods for a particular generic function, in this sense, will often be spread over several other packages. The total set of methods for a given generic function may change during a session, as additional packages are loaded. Each table must be consistent in the signature assumed for the generic function.

R distinguishes *standard* and *nonstandard* generic functions, with the former having a function body that does nothing but dispatch a method. For the most part, the distinction is just one of simplicity: knowing that a generic function only dispatches a method call allows some efficiencies and also removes some uncertainties.

In most cases, the generic function is the visible function corresponding to that name, in the corresponding package. There are two exceptions, *implicit* generic functions and the special computations required to deal with R's *primitive* functions. Packages can contain a table of implicit generic versions of functions in the package, if the package wishes to leave a function non-generic but to constrain what the function would be like if it were generic. Such implicit generic functions are created during the installation of the package, essentially by defining the generic function and possibly methods for it, and then reverting the function to its non-generic form. (See `implicitGeneric` for how this is done.) The mechanism is mainly used for functions in the older packages in R, which may prefer to ignore S4 methods. Even in this case, the actual mechanism is only needed if something special has to be specified. All functions have a corresponding implicit generic version defined automatically (an implicit, implicit generic function one might say). This function is a standard generic with the same arguments as the non-generic function, with the non-generic version as the default (and only) method, and with the generic signature being all the formal arguments except ....

The implicit generic mechanism is needed only to override some aspect of the default definition. One reason to do so would be to remove some arguments from the signature. Arguments that may need to be interpreted literally, or for which the lazy evaluation mechanism of the language is needed, must *not* be included in the signature of the generic function, since all arguments in the signature will be evaluated in order to select a method. For example, the argument `expr` to the function `with` is treated literally and must therefore be excluded from the signature.

One would also need to define an implicit generic if the existing non-generic function were not suitable as the default method. Perhaps the function only applies to some classes of objects, and the package designer prefers to have no general default method. In the other direction, the package designer might have some ideas about suitable methods for some classes, if the function were generic. With reasonably modern packages, the simple approach in all these cases is just to define the function as a generic. The implicit generic mechanism is mainly attractive for older packages that do not want to require the `methods` package to be available.

Generic functions will also be defined but not obviously visible for functions implemented as *primitive* functions in the base package. Primitive functions look like ordinary functions when printed but are in fact not function objects but objects of two types interpreted by the R evaluator to call underlying C code directly. Since their entire justification is efficiency, R refuses to hide primitives behind a generic function object. Methods may be defined for most primitives, and corresponding metadata objects will be created to store them. Calls to the primitive still go directly to the C code, which will sometimes check for applicable methods. The definition of “sometimes” is that methods must have been detected for the function in some package loaded in the session and `isS4(x)` is TRUE for the first argument (or for the second argument, in the case of binary operators). You can test whether methods have been detected by calling `isGeneric` for the relevant function and you can examine the generic function by calling `getGeneric`, whether or not methods have been detected. For more on generic functions, see the first reference and also section 2 of *R Internals*.

## Method Definitions

All method definitions are stored as objects from the `MethodDefinition` class. Like the class of generic functions, this class extends ordinary R functions with some additional slots: “generic”, containing the name and package of the generic function, and two signature slots, “defined” and “target”, the first being the signature supplied when the method was defined by a call to `setMethod`. The “target” slot starts off equal to the “defined” slot. When an inherited method is cached after being selected, as described above, a copy is made with the appropriate “target” signature. Output from `showMethods`, for example, includes both signatures.

Method definitions are required to have the same formal arguments as the generic function, since the method dispatch mechanism does not rematch arguments, for reasons of both efficiency and consistency.

## Examples

```
A class that extends a registered S3 class inherits that class S3
methods.

setClass("myFrame", contains = "data.frame",
 representation(timestamps = "POSIXt"))

df1 <- data.frame(x = 1:10, y = rnorm(10), z = sample(letters,10))

mydf1 <- new("myFrame", df1, timestamps = Sys.time())

"myFrame" objects inherit "data.frame" S3 methods; e.g., for [
```

```

mydf1[1:2,] # a data frame object (with extra attributes)

a method explicitly for "myFrame" class

setMethod("[",
 signature(x = "myFrame"),
 function (x, i, j, ..., drop = TRUE)
{
 S3Part(x) <- callNextMethod()
 x@timestamps <- c(Sys.time(), as.POSIXct(x@timestamps))
 x
}
)

mydf1[1:2,]

setClass("myDateTime", contains = "POSIXt")

now <- Sys.time() # class(now) is c("POSIXct", "POSIXt")
nowLt <- as.POSIXlt(now)# class(nowLt) is c("POSIXlt", "POSIXt")

mCt <- new("myDateTime", now)
mLt <- new("myDateTime", nowLt)

S3 methods for an S4 object will be selected using S4 inheritance
Objects mCt and mLt have different S3Class() values, but this is
not used.
f3 <- function(x)useMethod("f3") # an S3 generic to illustrate inheritance

f3.POSIXct <- function(x) "The POSIXct result"
f3.POSIXlt <- function(x) "The POSIXlt result"
f3.POSIXt <- function(x) "The POSIXt result"

stopifnot(identical(f3(mCt), f3.POSIXt(mCt)))
stopifnot(identical(f3(mLt), f3.POSIXt(mLt)))

An S4 object selects S3 methods according to its S4 "inheritance"

setClass("classA", contains = "numeric",
 representation(realData = "numeric"))

Math.classA <- function(x) {(getFunction(.Generic))(x@realData)}
setMethod("Math", "classA", Math.classA)

x <- new("classA", log(1:10), realData = 1:10)

stopifnot(identical(abs(x), 1:10))

setClass("classB", contains = "classA")

y <- new("classB", x)

```

```

stopifnot(identical(abs(y), 1:10)) # (version 2.9.0 or earlier fails here)

an S3 generic: just for demonstration purposes
f3 <- function(x, ...) UseMethod("f3")

f3.default <- function(x, ...) "Default f3"

S3 method (only) for classA
f3.classA <- function(x, ...) "Class classA for f3"

S3 and S4 method for numeric
f3.numeric <- function(x, ...) "Class numeric for f3"
setMethod("f3", "numeric", f3.numeric)

The S3 method for classA and the closest inherited S3 method for classB
are not found.

f3(x); f3(y) # both choose "numeric" method

to obtain the natural inheritance, set identical S3 and S4 methods
setMethod("f3", "classA", f3.classA)

f3(x); f3(y) # now both choose "classA" method

Need to define an S3 as well as S4 method to use on an S3 object
or if called from a package without the S4 generic

MathFun <- function(x) { # a smarter "data.frame" method for Math group
 for (i in seq(length = ncol(x))[sapply(x, is.numeric)])
 x[, i] <- (getFunction(.Generic))(x[, i])
 x
}
setMethod("Math", "data.frame", MathFun)

S4 method works for an S4 class containing data.frame,
but not for data.frame objects (not S4 objects)

try(logIris <- log(iris)) #gets an error from the old method

Define an S3 method with the same computation

Math.data.frame <- MathFun

logIris <- log(iris)

```

## Description

This class of objects was used in the original implementation of the package to control method dispatch. Its use is now deprecated, but object appear as the default method slot in generic functions. This and any other remaining uses will be removed in the future.

For the modern alternative, see [listOfMethods](#).

The details in this documentation are retained to allow analysis of old-style objects.

## Details

Suppose a function  $f$  has formal arguments  $x$  and  $y$ . The methods list object for that function has the object `as.name("x")` as its argument slot. An element of the methods named "track" is selected if the actual argument corresponding to  $x$  is an object of class "track". If there is such an element, it can generally be either a function or another methods list object.

In the first case, the function defines the method to use for any call in which  $x$  is of class "track". In the second case, the new methods list object defines the available methods depending on the remaining formal arguments, in this example,  $y$ .

Each method corresponds conceptually to a *signature*; that is a named list of classes, with names corresponding to some or all of the formal arguments. In the previous example, if selecting class "track" for  $x$ , finding that the selection was another methods list and then selecting class "numeric" for  $y$  would produce a method associated with the signature  $x = \text{"track"}, y = \text{"numeric"}$ .

## Slots

**argument:** Object of class "name". The name of the argument being used for dispatch at this level.

**methods:** A named list of the methods (and method lists) defined *explicitly* for this argument. The names are the names of classes, and the corresponding element defines the method or methods to be used if the corresponding argument has that class. See the details below.

**allMethods:** A named list, contains all the directly defined methods from the methods slot, plus any inherited methods. Ignored when methods tables are used for dispatch (see [Methods](#))

## Extends

Class "OptionalMethods", directly.

MethodWithNext-class    *Class MethodWithNext*

## Description

Class of method definitions set up for `callNextMethod`

## Objects from the Class

Objects from this class are generated as a side-effect of calls to [callNextMethod](#).

## Slots

.Data: Object of class "function"; the actual function definition.  
nextMethod: Object of class "PossibleMethod" the method to use in response to a `callNextMethod()` call.  
excluded: Object of class "list"; one or more signatures excluded in finding the next method.  
target: Object of class "signature", from class "MethodDefinition"  
defined: Object of class "signature", from class "MethodDefinition"  
generic: Object of class "character"; the function for which the method was created.

## Extends

Class "MethodDefinition", directly.  
Class "function", from data part.  
Class "PossibleMethod", by class "MethodDefinition".  
Class "OptionalMethods", by class "MethodDefinition".

## Methods

**findNextMethod** signature(method = "MethodWithNext"): used internally by method dispatch.  
**loadMethod** signature(method = "MethodWithNext"): used internally by method dispatch.  
**show** signature(object = "MethodWithNext")

## See Also

[callNextMethod](#), and class [MethodDefinition](#).

---

new

*Generate an Object from a Class*

---

## Description

Given the name or the definition of a class, plus optionally data to be included in the object, new returns an object from that class.

## Usage

```
new(Class, ...)
initialize(.Object, ...)
```

## Arguments

|         |                                                                                                                                                                         |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Class   | either the name of a class, a <code>character</code> string, (the usual case) or the object describing the class (e.g., the value returned by <code>getClass</code> ).  |
| ...     | data to include in the new object. Named arguments correspond to slots in the class definition. Unnamed arguments must be objects from classes that this class extends. |
| .Object | An object: see the Details section.                                                                                                                                     |

## Details

The function `new` begins by copying the prototype object from the class definition. Then information is inserted according to the `...` arguments, if any. As of version 2.4 of R, the type of the prototype object, and therefore of all objects returned by `new()`, is "S4" except for classes that extend one of the basic types, where the prototype has that basic type. User functions that depend on `typeof(object)` should be careful to handle "S4" as a possible type.

Note that the *name* of the first argument, "Class" entails that "Class" is an undesirable slot name in any formal class: `new("myClass", Class = <value>)` will not work.

The interpretation of the `...` arguments can be specialized to particular classes, if an appropriate method has been defined for the generic function "initialize". The `new` function calls `initialize` with the object generated from the prototype as the `.Object` argument to `initialize`.

By default, unnamed arguments in the `...` are interpreted as objects from a superclass, and named arguments are interpreted as objects to be assigned into the correspondingly named slots. Thus, explicit slots override inherited information for the same slot, regardless of the order in which the arguments appear.

The `initialize` methods do not have to have `...` as their second argument (see the examples). Initialize methods are often written when the natural parameters describing the new object are not the names of the slots. If you do define such a method, note the implications for future subclasses of your class. If these have additional slots, and your `initialize` method has `...` as a formal argument, then your method should pass such arguments along via `callNextMethod`. If your method does not have this argument, then either a subclass must have its own method or else the added slots must be specified by users in some way other than as arguments to `new`.

For examples of `initialize` methods, see [initialize-methods](#) for existing methods for classes "traceable" and "environment", among others. See the comments there on subclasses of "environment"; any `initialize` methods for these should be sure to allocate a new environment.

Methods for `initialize` can be inherited only by simple inheritance, since it is a requirement that the method return an object from the target class. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in [setIs](#) for the general concept.

Note that the basic vector classes, "numeric", etc. are implicitly defined, so one can use `new` for these classes.

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

## See Also

[Classes](#) for an overview of defining class, and [setOldClass](#) for the relation to S3 classes.

## Examples

```
using the definition of class "track" from \link{setClass}
```

```
a new object with two slots specified
t1 <- new("track", x = seq_along(ydata), y = ydata)

a new object including an object from a superclass, plus a slot
```

```

t2 <- new("trackCurve", t1, smooth = ysmooth)

define a method for initialize, to ensure that new objects have
equal-length x and y slots.

setMethod("initialize",
 "track",
 function(.Object, x = numeric(0), y = numeric(0)) {
 if(nargs() > 1) {
 if(length(x) != length(y))
 stop("specified x and y of different lengths")
 .Object@x <- x
 .Object@y <- y
 }
 .Object
 })

the next example will cause an error (x will be numeric(0)),
because we didnt build in defaults for x,
although we could with a more elaborate method for initialize

try(new("track", y = sort(stats::rnorm(10))))

a better way to implement the previous initialize method.
Why? By using callNextMethod to call the default initialize method
we dont inhibit classes that extend "track" from using the general
form of the new() function. In the previous version, they could only
use x and y as arguments to new, unless they wrote their own
initialize method.

setMethod("initialize", "track", function(.Object, ...) {
 .Object <- callNextMethod()
 if(length(.Object@x) != length(.Object@y))
 stop("specified x and y of different lengths")
 .Object
})

```

## Description

S4 classes that are defined to extend one of the basic vector classes should contain the class [structure](#) if they behave like structures; that is, if they should retain their class behavior under math functions or operators, so long as their length is unchanged. On the other hand, if their class depends on the values in the object, not just its structure, then they should lose that class under any such transformations. In the latter case, they should be defined to contain [nonStructure](#).

If neither of these strategies applies, the class likely needs some methods of its own for [Ops](#), [Math](#), and/or other generic functions. What is not usually a good idea is to allow such computations to drop down to the default, base code. This is inconsistent with most definitions of such classes.

## Methods

Methods are defined for operators and math functions (groups [Ops](#), [Math](#) and [Math2](#). In all cases the result is an ordinary vector of the appropriate type.

## ObjectsWithPackage-class

*A Vector of Object Names, with associated Package Names*

## Description

This class of objects is used to represent ordinary character string object names, extended with a package slot naming the package associated with each object.

## Objects from the Class

The function [getGenerics](#) returns an object of this class.

## Slots

**.Data:** Object of class "character": the object names.

**package:** Object of class "character" the package names.

## Extends

Class "character", from data part.

Class "vector", by class "character".

## See Also

Methods for general background.

---

**promptClass***Generate a Shell for Documentation of a Formal Class*

---

## Description

Assembles all relevant slot and method information for a class, with minimal markup for Rd processing; no QC facilities at present.

## Usage

```
promptClass(clName, filename = NULL, type = "class",
 keywords = "classes", where = topenv(parent.frame()),
 generatorName = clName)
```

## Arguments

|               |                                                                                                                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clName        | a character string naming the class to be documented.                                                                                                                                                                                                                  |
| filename      | usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is the topic name for the class documentation, followed by ".Rd". Can also be NA (see below). |
| type          | the documentation type to be declared in the output file.                                                                                                                                                                                                              |
| keywords      | the keywords to include in the shell of the documentation. The keyword "classes" should be one of them.                                                                                                                                                                |
| where         | where to look for the definition of the class and of methods that use it.                                                                                                                                                                                              |
| generatorName | the name for a generator function for this class; only required if a generator function was created <i>and</i> saved under a name different from the class name.                                                                                                       |

## Details

The class definition is found on the search list. Using that definition, information about classes extended and slots is determined.

In addition, the currently available generics with methods for this class are found (using [getGenerics](#)). Note that these methods need not be in the same environment as the class definition; in particular, this part of the output may depend on which packages are currently in the search list.

As with other prompt-style functions, unless filename is NA, the documentation shell is written to a file, and a message about this is given. The file will need editing to give information about the *meaning* of the class. The output of `promptClass` can only contain information from the metadata about the formal definition and how it is used.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where x is the list-style representation.

If a generator function is found assigned under the class name or the optional generatorName, skeleton documentation for that function is added to the file.

## Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

**See Also**

[prompt](#) for documentation of functions, [promptMethods](#) for documentation of method definitions.

For processing of the edited documentation, either use R CMD [Rdconv](#), or include the edited file in the ‘man’ subdirectory of a package.

**Examples**

```
Not run: > promptClass("track")
A shell of class documentation has been written to the
file "track-class.Rd".

End(Not run)
```

**promptMethods**

*Generate a Shell for Documentation of Formal Methods*

**Description**

Generates a shell of documentation for the methods of a generic function.

**Usage**

```
promptMethods(f, filename = NULL, methods)
```

**Arguments**

- |                 |                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>f</b>        | a character string naming the generic function whose methods are to be documented.                                                                                                                                                                                                                                                                                                |
| <b>filename</b> | usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to the coded topic name for these methods (currently, f followed by "-methods.Rd"). Can also be FALSE or NA (see below).                                                                                                      |
| <b>methods</b>  | Optional methods list object giving the methods to be documented. By default, the first methods object for this generic is used (for example, if the current global environment has some methods for f, these would be documented).<br><br>If this argument is supplied, it is likely to be <code>getMethods(f, where)</code> , with where some package containing methods for f. |

## Details

If `filename` is FALSE, the text created is returned, presumably to be inserted some other documentation file, such as the documentation of the generic function itself (see [prompt](#)).

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

Otherwise, the documentation shell is written to the file specified by `filename`.

## Value

If `filename` is FALSE, the text generated; if `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

ReferenceClasses

*Objects With Fields Treated by Reference (OOP-style)*

---

## Description

The software described here supports reference classes whose objects have fields accessed by reference in the style of “OOP” languages such as Java and C++. Computations with these objects invoke methods on them and extract or set their fields. The field and method computations potentially modify the object. All computations referring to the objects see the modifications, in contrast to the usual functional programming model in R. Reference classes can be used to program in R directly or in combination with an interface to an OOP-style language, allowing R-written methods to extend the interface.

## Usage

```
setRefClass(Class, fields = , contains = , methods = ,
 where =, ...)

getRefClass(Class, where =)
```

## Arguments

|       |                                                                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Class | character string name for the class.<br>In the call to <code>getRefClass()</code> this argument can also be any object from the relevant class; note also the corresponding reference class methods documented in the section on “Writing Reference Methods”. |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>fields</b>   | either a character vector of field names or a named list of the fields. The resulting fields will be accessed with reference semantics (see the section on “Reference Objects”). If the argument is a list, the elements of the list can be the character string name of a class, in which case the field must be from that class or a subclass.<br><br>The element in the list can alternatively be an <i>accessor function</i> , a function of one argument that returns the field if called with no argument or sets it to the value of the argument otherwise. Accessor functions are used internally and for inter-system interface applications. Their definition follows the rules for writing methods for the class: they can refer to other fields and can call other methods for this class or its superclasses. See the section on “Implementation” for the internal mechanism used by accessor functions. |
| <b>Note</b>     | Note that fields are distinct from the slots, if any, in the object. Slots are, as always, handled by standard R object management. It is not generally a good idea to mix slots and fields in the same class; this confuses the distinction in behavior between reference classes and regular S4 classes. See the comments in the “Implementation” section.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>contains</b> | optional vector of superclasses for this class. If a superclass is also a reference class, the fields and class-based methods will be inherited.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>methods</b>  | a named list of function definitions that can be invoked on objects from this class. These can also be created by invoking the \$methods method on the generator object returned. See the section on “Writing Reference Methods” for details.<br><br>Two optional method names are interpreted specially, initialize and finalize. If an initialize method is defined, it will be invoked when an object is generated from the class. See the discussion of method \$new(...) in the section “Reference Object Generators”.<br><br>If a finalize method is defined, a function will be registered to invoke it before the environment in the object is discarded by the garbage collector. See the matrix viewer example for both initialize and finalize methods.                                                                                                                                                    |
| <b>where</b>    | the environment in which to store the class definition (or to begin the search for it, in the case of getRefClass()). Defaults to the package namespace or environment for code that is part of an R package, and to the global environment for code sourced directly at the session top level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>...</b>      | other arguments to be passed to <a href="#">setClass</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Value

`setRefClass()` returns a generator function suitable for creating objects from the class, invisibly. A call to this function takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the fields and unnamed arguments, if any, that are objects from one of the superclasses of this class (but only superclasses that are themselves reference classes have any effect).

The generator function is similar to the S4 generator function returned by [setClass](#). In addition to being a generator function, however, it is also a reference class generator object, with reference class methods for various utilities. See the section on reference class generator objects below.

If the class has a method defined for `$initialize()`, this method will be called once the reference object has been created. You should write such a method for a class that needs to do some special initialization. In particular, a reference method is recommended rather than a method for the S4 generic function `initialize()`, because some special initialization is required for reference objects

*before* the initialization of fields. As with S4 classes, methods are written for `$initialize()` and not for `$new()`, both for the previous reason and also because `$new()` is invoked on the generator object and would be a method for that class.

The default method for `$initialize()` is equivalent to invoking the method `$initFields(...)`. Named arguments assign initial values to the corresponding fields. Unnamed arguments must be objects from this class or a reference superclass of this class. Fields will be initialized to the contents of the fields in such objects, but named arguments override the corresponding inherited fields. Note that fields are simply assigned. If the field is itself a reference object, that object is not copied. The new and previous object will share the reference. Also, a field assigned from an unnamed argument counts as an assignment for locked fields. To override an inherited value for a locked field, the new value must be one of the named arguments in the initializing call. A later assignment of the field will result in an error.

For technical reasons, the default method does not currently appear explicitly, but can be invoked by `$callSuper(...)` from a method for `$initialize()`. Initialization methods need some care in design, as they do for S4 classes. In particular, remember that others may subclass your class and pass through field assignments or other arguments. Therefore, your method should normally include ... as an argument, all other arguments should have defaults or check for missingness, and your method should pass all initialized values on via `$callSuper()` or `$initFields()` if you know that your superclasses have no initialization methods.

`getRefClass()` also returns the generator function for the class. Note that the package slot in the value is the correct package from the class definition, regardless of the `where` argument, which is used only to find the class if necessary.

## Reference Objects

Normal objects in R are passed as arguments in function calls consistently with functional programming semantics; that is, changes made to an object passed as an argument are local to the function call. The object that supplied the argument is unchanged.

The functional model (sometimes called pass-by-value, although this is inaccurate for R) is suitable for many statistical computations and is implicit, for example, in the basic R software for fitting statistical models. In some other situations, one would like all the code dealing with an object to see the exact same content, so that changes made in any computation would be reflected everywhere. This is often suitable if the object has some “objective” reality, such as a window in a user interface.

In addition, commonly used languages, including Java, C++ and many others, support a version of classes and methods assuming reference semantics. The corresponding programming mechanism is to invoke a method on an object. In the R syntax we use “\$” for this operation; one invokes a method, `m1`, on an object `x` by the expression `x$m1(...)`.

Methods in this paradigm are associated with the object, or more precisely with the class of the object, as opposed to methods in a function-based class/method system, which are fundamentally associated with the function (in R, for example, a generic function in an R session has a table of all its currently known methods). In this document “methods for a class” as opposed to “methods for a function” will make the distinction.

Objects in this paradigm usually have named fields on which the methods operate. In the R implementation, the fields are defined when the class is created. The field itself can optionally have a specified class, meaning that only objects from this class or one of its subclasses can be assigned to the field. By default, fields have class “ANY”. Fields may also be defined by supplying an accessor function which will be called to get or set the field. Accessor functions are likely when reference classes are part of an inter-system interface. The interface will usually supply the accessor functions automatically based on the definition of the corresponding class in the other language.

Fields are accessed by reference. In particular, invoking a method may modify the content of the fields.

Programming for such classes involves writing new methods for a particular class. In the R implementation, these methods are R functions, with zero or more formal arguments. The object on which the methods are invoked is not an explicit argument to the method. Instead, fields and methods for the class can be referred to by name in the method definition. The implementation uses R environments to make fields and methods available by name. Additional special fields allow reference to the complete object and to the definition of the class. See the section on “Writing Reference Methods”.

The goal of the software described here is to provide a uniform programming style in R for software dealing with reference classes, whether implemented directly in R or through an interface to one of the OOP languages.

### Writing Reference Methods

Reference methods are functions supplied as elements of a named list, either when invoking `g$methods()` on a generator object g or as the argument `methods` in a call to `setRefClass`. They are written as ordinary R functions but have some special features and restrictions. The body of the function can contain calls to any other reference method, including those inherited from other reference classes and may refer to fields in the object by name.

Fields may be modified in a method by using the non-local assignment operator, `<<-`, as in the `$edit` and `$undo` methods in the example below. Note that non-local assignment is required: a local assignment with the `<-` operator just creates a local object in the function call, as it would in any R function. When methods are installed, a heuristic check is made for local assignments to field names and a warning issued if any are detected.

Reference methods should be kept simple; if they need to do some specialized R computation, that computation should use a separate R function that is called from the reference method. Specifically, methods can not use special features of the enclosing environment mechanism, since the method’s environment is used to access fields and other methods. In particular, methods should not use non-exported entries in the package’s namespace, because the methods may be inherited by a reference class in another package.

Reference methods can not themselves be generic functions; if you want additional function-based method dispatch, write a separate generic function and call that from the method.

The entire object can be referred to in a method by the reserved name `.self`, as shown in the `save=` method of the example. The special object `.refClassDef` contains the definition of the class of the object. These fields are read-only (it makes no sense to modify these references), with one exception. In principle, the `.self` field can be modified in the `$initialize` method, because the object is still being created at this stage. This is definitely not recommended, unless to set some non-reference properties of the object defined for this class, which is itself not recommended if it mixes slots and fields.

The methods available include methods inherited from superclasses, as discussed in the next section. Only methods actually used will be included in the environment corresponding to an individual object. To declare that a method requires a particular other method, the first method should include a call to `$usingMethods()` with the name of the other method as an argument. Declaring the methods this way is essential if the other method is used indirectly (e.g., via `sapply()` or `do.call()`). If it is called directly, code analysis will find it. Declaring the method is harmless in any case, however, and may aid readability of the source code.

Documentation for the methods can be obtained by the `$help` method for the generator object. Methods for classes are not documented in the Rd format used for R functions. Instead, the `$help` method prints the calling sequence of the method, followed by self-documentation from the method definition, in the style of Python. If the first element of the body of the method is a literal character string (possibly multi-line), that string is interpreted as documentation. See the method definitions in the example.

## Inheritance

Reference classes inherit from other reference classes by using the standard R inheritance; that is, by including the superclasses in the `contains=` argument when creating the new class. The names of the reference superclasses are in slot `refSuperClasses` of the class definition. Reference classes can inherit from ordinary S4 classes also, but this is usually a bad idea if it mixes reference fields and non-reference slots. See the comments in the section on “Implementation”.

Class fields are inherited. A class definition can override a field of the same name in a superclass only if the overriding class is a subclass of the class of the inherited field. This ensures that a valid object in the field remains valid for the superclass as well.

Inherited methods are installed in the same way as directly specified methods. The code in a method can refer to inherited methods in the same way as directly specified methods.

A method may override a method of the same name in a superclass. The overriding method can call the superclass method by `callSuper(...)` as described below.

All reference classes inherit from the class “`envRefClass`”, which provides the following methods.

`$callSuper(...)` Calls the method inherited from a reference superclass. The call is meaningful only from within another method, and will be resolved to call the inherited method of the same name. The arguments to `$callSuper` are passed to the superclass version. See the matrix viewer class in the example.

Note that the intended arguments for the superclass method must be supplied explicitly; there is no convention for supplying the arguments automatically, in contrast to the similar mechanism for functional methods.

`$copy(shallow = FALSE)` Creates a copy of the object. With reference classes, unlike ordinary R objects, merely assigning the object with a different name does not create an independent copy. If `shallow` is `FALSE`, any field that is itself a reference object will also be copied, and similarly recursively for its fields. Otherwise, while reassigning a field to a new reference object will have no side effect, modifying such a field will still be reflected in both copies of the object. The argument has no effect on non-reference objects in fields. When there are reference objects in some fields but it is asserted that they will not be modified, using `shallow = TRUE` will save some memory and time.

`$field(name, value)` With one argument, returns the field of the object with character string `name`. With two arguments, the corresponding field is assigned `value`. Assignment checks that `name` specifies a valid field, but the single-argument version will attempt to get anything of that name from the object’s environment.

The `$field()` method replaces the direct use of a field name, when the name of the field must be calculated, or for looping over several fields.

`$export(Class)` Returns the result of coercing the object to `Class` (typically one of the superclasses of the object’s class). Calling the method has no side effect on the object itself.

`$getRefClass(); $getClass()` These return respectively the generator object and the formal class definition for the reference class of this object, efficiently.

`$import(value, Class = class(value))` Import the object `value` into the current object, replacing the corresponding fields in the current object. Object `value` must come from one of the superclasses of the current object’s class. If argument `Class` is supplied, `value` is first coerced to that class.

`$initFields(...)` Initialize the fields of the object from the supplied arguments. This method is usually only called from a class with a `$initialize()` method. It corresponds to the default initialization for reference classes. If there are slots and non-reference superclasses, these may be supplied in the `...` argument as well.

Typically, a specialized `$initialize()` method carries out its own computations, then invokes `$initFields()` to perform standard initialization, as shown in the `matrixViewer` class in the example below.

`$show()` This method is called when the object is printed automatically, analogously to the `show` function. A general method is defined for class "envRefClass". User-defined reference classes will often define their own method: see the Example below.

Note two points in the example. As with any `show()` method, it is a good idea to print the class explicitly to allow for subclasses using the method. Second, to call the *function* `show()` from the method, as opposed to the `$show()` method itself, refer to `methods::show()` explicitly.

`$trace(what, ...), $untrace(what)` Apply the tracing and debugging facilities of the `trace` function to the reference method `what`.

All the arguments of the `trace` function can be supplied, except for `signature`, which is not meaningful.

The reference method can be invoked on either an object or the generator for the class. See the section on Debugging below for details.

`$usingMethods(...)` Reference methods used by this method are named as the arguments either quoted or unquoted. In the code analysis phase of installing the present method, the declared methods will be included. It is essential to declare any methods used in a nonstandard way (e.g., via an `apply` function). Methods called directly do not need to be declared, but it is harmless to do so. `$usingMethods()` does nothing at run time.

Objects also inherit two reserved fields:

- .`self` a reference to the entire object;
- .`refClassDef` the class definition.

The defined fields should not override these, and in general it is unwise to define a field whose name begins with ". ", since the implementation may use such names for special purposes.

## Reference Class Generators

The call to `setRefClass` defines the specified class and returns a “generator function” object for that class. This object has class "refObjectGenerator"; it inherits from "function" via "classGeneratorFunction" and can be called to generate new objects from the reference class.

The returned object is also a reference class object, although not of the standard construction. It can be used to invoke reference methods and access fields in the usual way, but instead of being implemented directly as an environment it has a subsidiary generator object as a slot, a standard reference object (of class "refGeneratorSlot"). Note that if one wanted to extend the reference class generator capability with a subclass, this should be done by subclassing "refGeneratorSlot", not "refObjectGenerator".

The fields are `def`, the class definition, and `className`, the character string name of the class. Methods generate objects from the class, to access help on reference methods, and to define new reference methods for the class. The currently available methods are:

`$new(...)` This method is equivalent to calling the generator function returned by `setRefClass`.

`$help(topic)` Prints brief help on the topic. The topics recognized are reference method names, quoted or not.

The information printed is the calling sequence for the method, plus self-documentation if any. Reference methods can have an initial character string or vector as the first element in the body of the function defining the method. If so, this string is taken as self-documentation for the method (see the section on “Writing Reference Methods” for details).

If no topic is given or if the topic is not a method name, the definition of the class is printed.

`$methods(...)` With no arguments, returns a list of the reference methods for this class.

Named arguments are method definitions, which will be installed in the class, as if they had been supplied in the `methods` argument to `setRefClass()`. Supplying methods in this way, rather than in the call to `setRefClass()`, is largely for the sake of clearer source code when many or large methods are being defined. All methods for a class should be defined in the source code that defines the class, typically as part of a package. In particular, methods can not be redefined in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition.

The new methods can refer to any currently defined method by name (including other methods supplied in this call to `$methods()`). Note though that previously defined methods are not re-analyzed meaning that they will not call the new method (unless it redefines an existing method of the same name).

To remove a method, supply `NULL` as its new definition.

`$fields()` Returns a list of the fields, each with its corresponding class. Fields for which an accessor function was supplied in the definition have class "activeBindingFunction".

`$lock(...)` The fields named in the arguments are locked; specifically, after the lock method is called, the field may be set once. Any further attempt to set it will generate an error.

If called with no arguments, the method returns the names of the locked fields.

Fields that are defined by an explicit accessor function can not be locked (on the other hand, the accessor function can be defined to generate an error if called with an argument).

All code to lock fields should normally be part of the definition of a class; that is, the read-only nature of the fields is meant to be part of the class definition, not a dynamic property added later. In particular, fields can not be locked in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition. Locked fields can not be subsequently unlocked.

`$trace(what, ..., classMethod = FALSE)` Establish a traced version of method `what` for objects generated from this class. The generator object tracing works like the `$trace()` method for objects from the class, with two differences. Since it changes the method definition in the class object itself, tracing applies to all objects, not just the one on which the trace method is invoked.

Second, the optional argument `classMethod = TRUE` allows tracing on the methods of the generator object itself. By default, `what` is interpreted as the name of a method in the class for which this object is the generator.

`$accessors(...)` A number of systems using the OOP programming paradigm recommend or enforce *getter and setter methods* corresponding to each field, rather than direct access by name. If you like this style and want to extract a field named `abc` by `x$getAbc()` and assign it by `x$setAbc(value)`, the `$accessors` method is a convenience function that creates such getter and setter methods for the specified fields. Otherwise there is no reason to use this mechanism. In particular, it has nothing to do with the general ability to define fields by functions as described in the section on "Reference Objects".

## Implementation

Reference classes are implemented as S4 classes with a data part of type "environment". Fields correspond to named objects in the environment. A field associated with a function is implemented as an [active binding](#). In particular, fields with a specified class are implemented as a special form of active binding to enforce valid assignment to the field. A field, say `data`, can be accessed generally by an expression of the form `x$data` for any object from the relevant class. In a method for this class, the field can be accessed by the name `data`. A field that is not locked can be set by an expression of the form `x$data <- value`. Inside a method, a field can be assigned by an expression of the form `x <- value`. Note the [non-local assignment](#) operator. The standard R interpretation

of this operator works to assign it in the environment of the object. If the field has an accessor function defined, getting and setting will call that function.

When a method is invoked on an object, the function defining the method is installed in the object's environment, with the same environment as the environment of the function.

Because of the implementation, new reference classes can inherit from non-reference S4 classes as well as reference classes. This is usually a bad idea, if the slots from the non-reference class are thought of as alternatives to fields. Unless there is some special argument in favor, mixing the functional and reference paradigms for properties of the same object is conceptually unclear. In addition, the initialization method for the class will have to sort out fields from slots, with a good chance of creating anomalous behavior for subclasses of this class. Better in general to define fields analogous to the slots in the S4 class, and to initialize those from an S4 object of that class.

## Inter-System Interfaces

A number of languages use a similar reference-based programming model with classes and class-based methods. Aside from differences in choice of terminology and other details, many of these languages are compatible with the programming style described here. R interfaces to the languages exist in a number of packages.

The reference class definitions here provide a hook for classes in the foreign language to be exposed in R. Access to fields and/or methods in the class can be implemented by defining an R reference class corresponding to classes made available through the interface. Typically, the inter-system interface will take care of the details of creating the R class, given a description of the foreign class (what fields and methods it has, the classes for the fields, whether any are read-only, etc.) The specifics for the fields and methods can be implemented via reference methods for the R class. In particular, the use of active bindings allows field access for getting and setting, with actual access handled by the inter-system interface.

R methods and/or fields can be included in the class definition as for any reference class. The methods can use or set fields and can call other methods transparently whether the field or method comes from the interface or is defined directly in R.

For an inter-system interface using this approach, see the code for package Rcpp, version 0.8.7 or later.

## Debugging

The standard R debugging and tracing facilities can be applied to reference methods. Reference methods can be passed to `debug` and its relatives from an object to debug further method invocations on that object; for example, `debug(xx$edit)`.

Somewhat more flexible use is available for a reference method version of the `trace` function. A corresponding `$trace()` reference method is available for either an object or for the reference class generator (`xx$trace()` or `mEdit$trace()` in the example below). Using `$trace()` on an object sets up a tracing version for future invocations of the specified method for that object. Using `$trace()` on the generator for the class sets up a tracing version for all future objects from that class (and sometimes for existing objects from the class if the method is not declared or previously invoked).

In either case, all the arguments to the standard `trace` function are available, except for `signature=` which is meaningless since reference methods can not be S4 generic functions. This includes the typical style `trace(what, browser)` for interactive debugging and `trace(what, edit = TRUE)` to edit the reference method interactively.

**Examples**

```
a simple editor for matrix objects. Method $edit() changes some
range of values; method $undo() undoes the last edit.
mEdit <- setRefClass("mEdit",
 fields = list(data = "matrix",
 edits = "list"),
 methods = list(
 edit = function(i, j, value) {
 ## the following string documents the edit method
 Replaces the range [i, j] of the
 object by value.

 backup <-
 list(i, j, data[i,j])
 data[i,j] <- value
 edits <- c(edits, list(backup))
 invisible(value)
 },
 undo = function() {
 Undoes the last edit() operation
 and update the edits field accordingly.

 prev <- edits
 if(length(prev)) prev <- prev[[length(prev)]]
 else stop("No more edits to undo")
 edit(prev[[1]], prev[[2]], prev[[3]])
 ## trim the edits list
 length(edits) <- length(edits) - 2
 invisible(prev)
 },
 show = function() {
 Method for automatically printing matrix editors
 cat("Reference matrix editor object of class",
 classLabel(class(.self)), "\n")
 cat("Data: \n")
 methods::show(data)
 cat("Undo list is of length", length(edits), "\n")
 }
))

xMat <- matrix(1:12,4,3)
xx <- mEdit(data = xMat)
xx$edit(2, 2, 0)
xx
xx$undo()
mEdit$help("undo")
stopifnot(all.equal(xx$data, xMat))

utils::str(xx) # show fields and names of non-trivial methods

add a method to save the object
mEdit$methods(
```

```

save = function(file) {
 Save the current object on the file
 in R external object format.

 base::save(.self, file = file)
}

tf <- tempfile()
xx$save(tf)

Not run:
Inheriting a reference class: a matrix viewer

```

## Description

These are old utility functions to construct, respectively a list designed to represent the slots and superclasses and a list of prototype specifications. The `representation()` function is no longer useful, since the arguments `slots` and `contains` to `setClass` are now recommended.

The `prototype()` function may still be used for the corresponding argument, but a simple list of the same arguments works as well.

## Usage

```
representation(...)
prototype(...)
```

## Arguments

...

The call to `representation` takes arguments that are single character strings. Unnamed arguments are classes that a newly defined class extends; named arguments name the explicit slots in the new class, and specify what class each slot should have.

In the call to `prototype`, if an unnamed argument is supplied, it unconditionally forms the basis for the prototype object. Remaining arguments are taken to correspond to slots of this object. It is an error to supply more than one unnamed argument.

## Details

The `representation` function applies tests for the validity of the arguments. Each must specify the name of a class.

The classes named don't have to exist when `representation` is called, but if they do, then the function will check for any duplicate slot names introduced by each of the inherited classes.

The arguments to `prototype` are usually named initial values for slots, plus an optional first argument that gives the object itself. The unnamed argument is typically useful if there is a data part to the definition (see the examples below).

## Value

The value of `representation` is just the list of arguments, after these have been checked for validity.

The value of `prototype` is the object to be used as the prototype. Slots will have been set consistently with the arguments, but the construction does *not* use the class definition to test validity of the contents (it hardly can, since the prototype object is usually supplied to create the definition).

`setClass`

## Examples

```

representation for a new class with a directly define slot "smooth"
which should be a "numeric" object, and extending class "track"
representation("track", smooth ="numeric")

setClass("Character",representation("character"))
setClass("TypedCharacter",representation("Character",type="character"),
 prototype(character(0),type="plain"))
ttt <- new("TypedCharacter", "foo", type = "character")

setClass("num1", representation(comment = "character"),
 contains = "numeric",
 prototype = prototype(pi, comment = "Start with pi"))

```

## Description

Old-style (S3) classes may be registered as S4 classes (by calling [setOldClass](#), and many have been. These classes can then be contained in (that is, superclasses of) regular S4 classes, allowing formal methods and slots to be added to the S3 behavior. The function [S3Part](#) extracts or replaces the S3 part of such an object. [S3Class](#) extracts or replaces the S3-style class. [S3Class](#) also applies to object from an S4 class with `S3methods=TRUE` in the call to [setClass](#).

See the details below. Also discussed are S3  $\leftrightarrow$  S4 coercion; see the section “S3 and S4 objects”

## Usage

```

S3Part(object, strictS3 = FALSE, S3Class)

S3Part(object, strictS3 = FALSE, needClass =) <- value

S3Class(object)

S3Class(object) <- value

isXS3Class(classDef)

slotsFromS3(object)

```

## Arguments

|                     |                                                                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | An object from some class that extends a registered S3 class, usually because the class has as one of its superclasses an S3 class registered by a call to <a href="#">setOldClass</a> , or from a class that extends a basic vector, matrix or array object type. See the details. |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | For most of the functions, an S3 object can also be supplied, with the interpretation that it is its own S3 part.                                                                                                                                                                                                                                                                                                                                                                                      |
| strictS3  | If TRUE, the value returned by <code>S3Part</code> will be an S3 object, with all the S4 slots removed. Otherwise, an S4 object will always be returned; for example, from the S4 class created by <code>setOldClass</code> as a proxy for an S3 class, rather than the underlying S3 object.                                                                                                                                                                                                          |
| S3Class   | The character vector to be stored as the S3 class slot in the object. Usually, and by default, retains the slot from <code>object</code> .                                                                                                                                                                                                                                                                                                                                                             |
| needClass | Require that the replacement value be this class or a subclass of it.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| value     | For <code>S3Part&lt;-</code> , the replacement value for the S3 part of the object. This does <i>not</i> need to be an S4 object; in fact, the usual way to create objects from these classes is by giving an S3 object of the right class as an argument to <code>new</code> .<br>For <code>S3Class&lt;-</code> , the character vector that will be used as a proxy for <code>class(x)</code> in S3 method dispatch. This replacement function can be used to control S3 per-object method selection. |
| classDef  | A class definition object, as returned by <code>getClass</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Details

Classes that register S3 classes by a call to `setOldClass` have slot ".S3Class" to hold the corresponding S3 vector of class strings. The prototype of such a class has the value for this slot determined by the argument to `setOldClass`. Other S4 classes will have the same slot if the argument `S3methods = TRUE` is supplied to `setClass`; in this case, the slot is set to the S4 inheritance of the class.

New S4 classes that extend (contain) such classes also have the same slot, and by default the prototype has the value determined by the `contains=` argument to `setClass`. Individual objects from the S4 class may have an S3 class corresponding to the value in the prototype or to an (S3) subclass of that value. See the examples below.

`S3Part()` with `strictS3 = TRUE` constructs the underlying S3 object by eliminating all the formally defined slots and turning off the S4 bit of the object. With `strictS3 = FALSE` the object returned is from the corresponding S4 class. For consistency and generality, `S3Part()` works also for classes that extend the basic vector, matrix and array classes. Since R is somewhat arbitrary about what it treats as an S3 class ("ts" is, but "matrix" is not), `S3Part()` tries to return an S3 (that is, non-S4) object whenever the S4 class has a suitable superclass, of either S3 or basic object type.

One general application that relies on this generality is to use `S3Part()` to get a superclass object that is guaranteed not to be an S4 object. If you are calling some function that checks for S4 objects, you need to be careful not to end up in a closed loop (`fooS4` calls `fooS3`, which checks for an S4 object and calls `fooS4` again, maybe indirectly). Using `S3Part()` with `strictS3 = TRUE` is a mechanism to avoid such loops.

Because the contents of S3 class objects have no definition or guarantee, the computations involving S3 parts do *not* check for slot validity. Slots are implemented internally in R as attributes, which are copied when present in the S3 part. Grave problems can occur if an S4 class extending an S3 class uses the name of an S3 attribute as the name of an S4 slot, and S3 code sets the attribute to an object from an invalid class according to the S4 definition.

Frequently, `S3Part` can and should be avoided by simply coercing objects to the desired class; methods are automatically defined to deal correctly with the slots when `as` is called to extract or replace superclass objects.

The function `slotsFromS3()` is a generic function used internally to access the slots associated with the S3 part of the object. Methods for this function are created automatically when `setOldClass` is

called with the `S4Class` argument. Usually, there is only one S3 slot, containing the S3 class, but the `S4Class` argument may provide additional slots, in the case that the S3 class has some guaranteed attributes that can be used as formal S4 slots. See the corresponding section in the documentation of `setOldClass`.

### Value

`S3Part`: Returns or sets the S3 information (and possibly some S4 slots as well, depending on arguments `S3Class` and `keepSlots`). See the discussion of argument `strict` above. If it is TRUE the value returned is an S3 object.

`S3Class`: Returns or sets the character vector of S3 class(es) stored in the object, if the class has the corresponding `.S3Class` slot. Currently, the function defaults to `class` otherwise.

`isXS3Class`: Returns TRUE or FALSE according to whether the class defined by `ClassDef` extends S3 classes (specifically, whether it has the slot for holding the S3 class).

`slotsFromS3`: returns a list of the relevant slot classes, or an empty list for any other object.

### S3 and S4 Objects: Conversion Mechanisms

Objects in R have an internal bit that indicates whether or not to treat the object as coming from an S4 class. This bit is tested by `isS4` and can be set on or off by `asS4`. The latter function, however, does no checking or interpretation; you should only use it if you are very certain every detail has been handled correctly.

As a friendlier alternative, methods have been defined for coercing to the virtual classes "S3" and "S4". The expressions `as(object, "S3")` and `as(object, "S4")` return S3 and S4 objects, respectively. In addition, they attempt to do conversions in a valid way, and also check validity when coercing to S4.

The expression `as(object, "S3")` can be used in two ways. For objects from one of the registered S3 classes, the expression will ensure that the class attribute is the full multi-string S3 class implied by `class(object)`. If the registered class has known attribute/slots, these will also be provided.

Another use of `as(object, "S3")` is to take an S4 object and turn it into an S3 object with corresponding attributes. This is only meaningful with S4 classes that have a data part. If you want to operate on the object without invoking S4 methods, this conversion is usually the safest way.

The expression `as(object, "S4")` will use the attributes in the object to create an object from the S4 definition of `class(object)`. This is a general mechanism to create partially defined version of S4 objects via S3 computations (not much different from invoking `new` with corresponding arguments, but usable in this form even if the S4 object has an initialize method with different arguments).

`setOldClass`

## Examples

```

two examples extending S3 class "lm", class "xlm" directly
and "ylm" indirectly
setClass("xlm", representation(eps = "numeric"), contains = "lm")
setClass("ylm", representation(header = "character"), contains = "xlm")

lm.D9 is as computed in the example for stats:::lm
y1 = new("ylm", lm.D9, header = "test", eps = .1)
xx = new("xlm", lm.D9, eps = .1)
y2 = new("ylm", xx, header = "test")
stopifnot(inherits(y2, "lm"))
stopifnot(identical(y1, y2))
stopifnot(identical(S3Part(y1, strict = TRUE), lm.D9))

note the these classes can insert an S3 subclass of "lm" as the S3 part:
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData) # S3 class: c("mlm", "lm")
ym1 = new("ylm", myLm, header = "Example", eps = 0.)

##similar classes to "xlm" and "ylm", but extending S3 class c("mlm", "lm")
setClass("xmm", representation(eps = "numeric"), contains = "mlm")
setClass("ymm", representation(header="character"), contains = "xmm")

ym2 <- new("ymm", myLm, header = "Example2", eps = .001)

but for class "ymm", an S3 part of class "lm" is an error:
try(new("ymm", lm.D9, header = "Example2", eps = .001))

setClass("dataFrameD", representation(date = "Date"),
 contains = "data.frame")
myDD <- new("dataFrameD", myData, date = Sys.Date())

S3Part() applied to classes with a data part (.Data slot)

setClass("NumX", contains="numeric", representation(id="character"))
nn = new("NumX", 1:10, id="test")
stopifnot(identical(1:10, S3Part(nn, strict = TRUE)))

m1 = cbind(group, weight)
setClass("MatX", contains = "matrix", representation(date = "Date"))
mx1 = new("MatX", m1, date = Sys.Date())
stopifnot(identical(m1, S3Part(mx1, strict = TRUE)))

```

## Description

Methods can be defined for *group generic functions*. Each group generic function has a number of *member generic functions* associated with it.

Methods defined for a group generic function cause the same method to be defined for each member of the group, but a method explicitly defined for a member of the group takes precedence over a method defined, with the same signature, for the group generic.

The functions shown in this documentation page all reside in the **methods** package, but the mechanism is available to any programmer, by calling [setGroupGeneric](#) (provided package **methods** is attached).

## Usage

```
S4 group generics:
Arith(e1, e2)
Compare(e1, e2)
Ops(e1, e2)
Logic(e1, e2)
Math(x)
Math2(x, digits)
Summary(x, ..., na.rm = FALSE)
Complex(z)
```

## Arguments

|                           |                                                                            |
|---------------------------|----------------------------------------------------------------------------|
| <code>x, z, e1, e2</code> | objects.                                                                   |
| <code>digits</code>       | number of digits to be used in <code>round</code> or <code>signif</code> . |
| <code>...</code>          | further arguments passed to or from methods.                               |
| <code>na.rm</code>        | logical: should missing values be removed?                                 |

## Details

Methods can be defined for the group generic functions by calls to [setMethod](#) in the usual way. Note that the group generic functions should never be called directly – a suitable error message will result if they are. When metadata for a group generic is loaded, the methods defined become methods for the members of the group, but only if no method has been specified directly for the member function for the same signature. The effect is that group generic definitions are selected before inherited methods but after directly specified methods. For more on method selection, see [Methods](#).

There are also S3 groups `Math`, `Ops`, `Summary` and `Complex`, see [?S3groupGeneric](#), with no corresponding R objects, but these are irrelevant for S4 group generic functions.

The members of the group defined by a particular generic can be obtained by calling [getGroupMembers](#). For the group generic functions currently defined in this package the members are as follows:

```
Arith "+", "-", "*", "^", "%%", "%/%", "/"
Compare "==", ">", "<", "!=" , "<=", ">="
Logic "&", "|".
Ops "Arith", "Compare", "Logic"
Math "abs", "sign", "sqrt", "ceiling", "floor", "trunc", "cummax", "cummin", "cumprod",
 "cumsum", "log", "log10", "log2", "log1p", "acos", "acosh", "asin", "asinh", "atan",
 "atanh", "exp", "expm1", "cos", "cosh", "sin", "sinh", "tan", "tanh", "gamma",
 "lgamma", "digamma", "trigamma"
Math2 "round", "signif"
```

```
Summary "max", "min", "range", "prod", "sum", "any", "all"
Complex "Arg", "Conj", "Im", "Mod", "Re"
```

Note that Ops merely consists of three sub groups.

All the functions in these groups (other than the group generics themselves) are basic functions in R. They are not by default S4 generic functions, and many of them are defined as primitives. However, you can still define formal methods for them, both individually and via the group generics. It all works more or less as you might expect, admittedly via a bit of trickery in the background. See [Methods](#) for details.

Note that two members of the Math group, `log` and `trunc`, have ... as an extra formal argument. Since methods for Math will have only one formal argument, you must set a specific method for these functions in order to call them with the extra argument(s).

For further details about group generic functions see section 10.5 of *Software for Data Analysis*.

## See Also

The function `callGeneric` is nearly always relevant when writing a method for a group generic. See the examples below and in section 10.5 of *Software for Data Analysis*.

See [S3groupGeneric](#) for S3 group generics.

## Examples

```
setClass("testComplex", representation(zz = "complex"))
method for whole group "Complex"
setMethod("Complex", "testComplex",
 function(z) c("groupMethod", callGeneric(z@zz)))
exception for Arg() :
setMethod("Arg", "testComplex",
 function(z) c("ArgMethod", Arg(z@zz)))
z1 <- 1+2i
z2 <- new("testComplex", zz = z1)
stopifnot(identical(Mod(z2), c("groupMethod", Mod(z1))))
stopifnot(identical(Arg(z2), c("ArgMethod", Arg(z1))))
```

SClassExtension-class *Class to Represent Inheritance (Extension) Relations*

## Description

An object from this class represents a single ‘is’ relationship; lists of these objects are used to represent all the extensions (superclasses) and subclasses for a given class. The object contains information about how the relation is defined and methods to coerce, test, and replace correspondingly.

## Objects from the Class

Objects from this class are generated by [setIs](#), from direct calls and from the contains= information in a call to [setClass](#), and from class unions created by [setClassUnion](#). In the last case, the information is stored in defining the *subclasses* of the union class (allowing unions to contain sealed classes).

## Slots

**subClass, superClass:** The classes being extended: corresponding to the from, and to arguments to [setIs](#).

**package:** The package to which that class belongs.

**coerce:** A function to carry out the as() computation implied by the relation. Note that these functions should *not* be used directly. They only deal with the strict=TRUE calls to the as function, with the full method constructed from this mechanically.

**test:** The function that would test whether the relation holds. Except for explicitly specified test arguments to [setIs](#), this function is trivial.

**replace:** The method used to implement as(x,      Class) <- value.

**simple:** A "logical" flag, TRUE if this is a simple relation, either because one class is contained in the definition of another, or because a class has been explicitly stated to extend a virtual class. For simple extensions, the three methods are generated automatically.

**by:** If this relation has been constructed transitively, the first intermediate class from the subclass.

**dataPart:** A "logical" flag, TRUE if the extended class is in fact the data part of the subclass. In this case the extended class is a basic class (i.e., a type).

**distance:** The distance between the two classes, 1 for directly contained classes, plus the number of generations between otherwise.

## Methods

No methods defined with class "SClassExtension" in the signature.

## See Also

[is](#), [as](#), and the [classRepresentation](#) class.

[selectSuperClasses](#)      *Super Classes (of Specific Kinds) of a Class*

## Description

Return superclasses of ClassDef, possibly only non-virtual or direct or simple ones.

These functions are designed to be fast, and consequently only work with the contains slot of the corresponding class definitions.

## Usage

```
selectSuperClasses(Class, dropVirtual = FALSE, namesOnly = TRUE,
 directOnly = TRUE, simpleOnly = directOnly,
 where = topenv(parent.frame()))

.selectSuperClasses(ext, dropVirtual = FALSE, namesOnly = TRUE,
 directOnly = TRUE, simpleOnly = directOnly)
```

### Arguments

|             |                                                                                                                                            |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Class       | name of the class or (more efficiently) the class definition object (see <a href="#">getClass</a> ).                                       |
| dropVirtual | logical indicating if only non-virtual superclasses should be returned.                                                                    |
| namesOnly   | logical indicating if only a vector names instead of a named list class-extensions should be returned.                                     |
| directOnly  | logical indicating if only a <i>direct</i> super classes should be returned.                                                               |
| simpleOnly  | logical indicating if only simple class extensions should be returned.                                                                     |
| where       | (only used when Class is not a class definition) environment where the class definition of Class is found.                                 |
| ext         | for <code>.selectSuperClasses()</code> only, a <a href="#">list</a> of class extensions, typically <code>getClassDef(..)@contains</code> . |

### Value

a [character](#) vector (if namesOnly is true, as per default) or a list of class extensions (as the contains slot in the result of [getClass](#)).

### Note

The typical user level function is `selectSuperClasses()` which calls `.selectSuperClasses()`; i.e., the latter should only be used for efficiency reasons by experienced useRs.

### See Also

[is](#), [getClass](#); further, the more technical class [classRepresentation](#) documentation.

### Examples

```
setClass("Root")
setClass("Base", contains = "Root", representation(length = "integer"))
setClass("A", contains = "Base", representation(x = "numeric"))
setClass("B", contains = "Base", representation(y = "character"))
setClass("C", contains = c("A", "B"))

extends("C") #--> "C" "A" "B" "Base" "Root"
selectSuperClasses("C") # "A" "B"
selectSuperClasses("C", direct=FALSE) # "A" "B" "Base" "Root"
selectSuperClasses("C", dropVirt = TRUE, direct=FALSE) # ditto w/o "Root"
```

### Description

Create a class definition, specifying the representation (the slots) and/or the classes contained in this one (the superclasses), plus other optional details. As a side effect, the class definition is stored in the specified environment. A generator function is returned as the value of `setClass()`, suitable for creating objects from the class if the class is not virtual. Of the many arguments to the function only `Class`, `slots=` and `contains=` are usually needed.

**Usage**

```
setClass(Class, representation, prototype, contains=character(),
 validity, access, where, version, sealed, package,
 S3methods = FALSE, slots)
```

**Arguments**

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Class                                      | character string name for the class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| slots                                      | a named list or named character vector. The names are the names of the slots in the new class and the elements are the character string names of the corresponding classes.<br><br>In rare cases where there is ambiguity about the class of a slot, because two classes of the same name are imported from different packages, the corresponding element of the argument must have a "package" attribute to disambiguate the choice.                                                                                                                                 |
|                                            | It is allowed to provide an unnamed character vector as a limiting case, with the elements taken as slot names and all slots having the unrestricted class "ANY".                                                                                                                                                                                                                                                                                                                                                                                                     |
| contains                                   | the names (and optionally package slots) for the <i>superclasses</i> of this class. The special superclass "VIRTUAL" causes the new class to be created as a virtual class; see the section on virtual classes in <a href="#">Classes</a> .                                                                                                                                                                                                                                                                                                                           |
| prototype                                  | an object providing the default data for the slots in this class. By default, each will be the prototype object for the superclass. If provided, using a call to <a href="#">prototype</a> will carry out some checks.                                                                                                                                                                                                                                                                                                                                                |
| where                                      | the environment in which to store the definition. Should not be supplied in standard use. For calls to <a href="#">setClass()</a> appearing in the source code for a package, will default to the namespace of the package. For calls typed or sourced at the top level in a session, will default to the global environment.                                                                                                                                                                                                                                         |
| validity                                   | if supplied, should be a validity-checking method for objects from this class (a function that returns TRUE if its argument is a valid object of this class and one or more strings describing the failures otherwise). See <a href="#">validObject</a> for details.                                                                                                                                                                                                                                                                                                  |
| S3methods, representation, access, version | All these arguments are deprecated from version 3.0.0 of R and should be avoided.<br><br>S3methods is a flag indicating that old-style methods will be written involving this class. Modern versions of R attempt to match formal and old-style methods consistently, so this argument is largely irrelevant.<br><br>representation is an argument inherited from S that included both slots and contains, but the use of the latter two arguments is clearer and recommended. access and version are included for historical compatibility with S-Plus, but ignored. |
| sealed                                     | if TRUE, the class definition will be sealed, so that another call to <a href="#">setClass</a> will fail on this class name.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| package                                    | an optional package name for the class. Should very rarely be used. By default the name of the package in which the class definition is assigned.                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Value**

A generator function suitable for creating objects from the class is returned, invisibly. A call to this function generates a call to [new](#) for the class. The call takes any number of arguments, which will

be passed on to the initialize method. If no `initialize` method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the slots.

Typically the generator function is assigned the name of the class, for programming clarity. This is not a requirement and objects from the class can also be generated directly from `new`. The advantages of the generator function are a slightly simpler and clearer call, and that the call will contain the package name of the class (eliminating any ambiguity if two classes from different packages have the same name).

If the class is virtual, an attempt to generate an object from either the generator or `new()` will result in an error.

### Basic Use: Slots and Inheritance

The two essential arguments other than the class name are `slots` and `contains`, defining the explicit slots and the inheritance (superclasses). Together, these arguments define all the information in an object from this class; that is, the names of all the slots and the classes required for each of them.

The name of the class determines which methods apply directly to objects from this class. The inheritance information specifies which methods apply indirectly, through inheritance. See [Methods](#).

The slots in a class definition will be the union of all the slots specified directly by `slots` and all the slots in all the contained classes. There can only be one slot with a given name; specifically, the direct and inherited slot names must be unique. That does not, however, prevent the same class from being inherited via more than one path.

One kind of element in the `contains=` argument is special, specifying one of the R object types or one of a few other special R types (`matrix` and `array`). See the section on inheriting from object types, below.

Slot names "class" and "Class" are not allowed. There are other slot names with a special meaning; these names start with the ". ." character. To be safe, you should define all of your own slots with names starting with an alphabetic character.

### Inheriting from Object Types

In addition to containing other S4 classes, a class definition can contain either an S3 class (see the next section) or a built-in R pseudo-class—one of the R object types or one of the special R pseudo-classes "matrix" and "array". A class can contain at most one of the object types, directly or indirectly. When it does, that contained class determines the "data part" of the class.

Objects from the new class try to inherit the built in behavior of the contained type. In the case of normal R data types, including vectors, functions and expressions, the implementation is relatively straightforward. For any object `x` from the class, `typeof(x)` will be the contained basic type; and a special pseudo-slot, `.Data`, will be shown with the corresponding class. See the "numWithId" example below.

Classes may also inherit from "vector", "matrix" or "array". The data part of these objects can be any vector data type.

For an object from any class that does *not* contain one of these types or classes, `typeof(x)` will be "S4".

Some R data types do not behave normally, in the sense that they are non-local references or other objects that are not duplicated. Examples include those corresponding to classes "environment", "externalptr", and "name". These can not be the types for objects with user-defined classes (either S4 or S3) because setting an attribute overwrites the object in all contexts. It is possible to define a class that inherits from such types, through an indirect mechanism that stores the inherited object in a reserved slot. See the example for class "stampedEnv" below. S3 method dispatch and

the relevant `as.type()` functions should behave correctly, but code that uses the type of the object directly will not.

Also, keep in mind that the object passed to low-level computations will be the underlying object type, *without* any of the slots defined in the class. To return the full information, you will usually have to define a method that sets the data part.

### Inheriting from S3 Classes

Old-style S3 classes have no formal definition. Objects are “from” the class when their class attribute contains the character string considered to be the class name.

Using such classes with formal classes and methods is necessarily a risky business, since there are no guarantees about the content of the objects or about consistency of inherited methods. Given that, it is still possible to define a class that inherits from an S3 class, providing that class has been registered as an old class (see `setOldClass`).

Broadly speaking, both S3 and S4 method dispatch try to behave sensibly with respect to inheritance in either system. Given an S4 object, S3 method dispatch and the `inherits` function should use the S4 inheritance information. Given an S3 object, an S4 generic function will dispatch S4 methods using the S3 inheritance, provided that inheritance has been declared via `setOldClass`.

### Classes and Packages

Class definitions normally belong to packages (but can be defined in the global environment as well, by evaluating the expression on the command line or in a file sourced from the command line). The corresponding package name is part of the class definition; that is, part of the `classRepresentation` object holding that definition. Thus, two classes with the same name can exist in different packages, for most purposes.

When a class name is supplied for a slot or a superclass in a call to `setClass`, a corresponding class definition will be found, looking from the namespace of the current package, assuming the call in question appears directly in the source for the package, as it should to avoid ambiguity. The class definition must be found in the namespace of the current package, in the imports for that namespace or in the basic classes defined by the `methods` package. (The `methods` package must be included in the `Depends` directive of the package’s “DESCRIPTION” file in order for the “CMD check” utility to find these classes.)

When this rule does not identify a class uniquely (because it appears in more than one imported package) then the `packageSlot` of the character string name needs to be supplied with the name. This should be a rare occurrence.

## Examples

```

A simple class with two slots
track <- setClass("track",
 slots = c(x="numeric", y="numeric"))
an object from the class
t1 <- track(x = 1:10, y = 1:10 + rnorm(10))

A class extending the previous, adding one more slot
trackCurve <- setClass("trackCurve",
 slots = c(smooth = "numeric"),
 contains = "track")

an object containing a superclass object
t1s <- trackCurve(t1, smooth = 1:10)

A class similar to "trackCurve", but with different structure
allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
 slots = c(x="numeric", y="matrix", smooth="matrix"),
 prototype = list(x=numeric(), y=matrix(0,0,0),
 smooth= matrix(0,0,0)))
See ?setIs for further examples using these classes

A class that extends the built-in data type "numeric"

numWithId <- setClass("numWithId", slots = c(id = "character"),
 contains = "numeric")

numWithId(1:3, id = "An Example")

inherit from reference object of type "environment"
stampedEnv <- setClass("stampedEnv", contains = "environment",
 slots = c(update = "POSIXct"))
setMethod("[[<-", c("stampedEnv", "character", "missing"),
 function(x, i, j, ..., value) {
 ev <- as(x, "environment")
 ev[[i]] <- value #update the object in the environment
 x@update <- Sys.time() # and the update time
 x})

e1 <- stampedEnv(update = Sys.time())

e1[["noise"]] <- rnorm(10)

```

## Description

A class may be defined as the *union* of other classes; that is, as a virtual class defined as a superclass of several other classes. Class unions are useful in method signatures or as slots in other classes, when we want to allow one of several classes to be supplied.

## Usage

```
setClassUnion(name, members, where)
isClassUnion(Class)
```

## Arguments

|                      |                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>    | the name for the new union class.                                                                                                                                                                                |
| <code>members</code> | the classes that should be members of this union.                                                                                                                                                                |
| <code>where</code>   | where to save the new class definition; by default, the environment of the package in which the <code>setClassUnion</code> call appears, or the global environment if called outside of the source of a package. |
| <code>Class</code>   | the name or definition of a class.                                                                                                                                                                               |

## Details

The classes in `members` must be defined before creating the union. However, members can be added later on to an existing union, as shown in the example below. Class unions can be members of other class unions.

The prototype object in the class union definition will be `NULL` if class "NULL" is a member of the union and the prototype object of the first member class otherwise (as of version 2.15.0 of R; earlier versions had a `NULL` prototype even if that was not valid).

Class unions are the only way to create a class that is extended by a class whose definition is sealed (for example, the basic datatypes or other classes defined in the base or methods package in R are sealed). You cannot say `setIs("function", "other")` unless "other" is a class union. In general, a `setIs` call of this form changes the definition of the first class mentioned (adding "other" to the list of superclasses contained in the definition of "function").

Class unions get around this by not modifying the first class definition, relying instead on storing information in the subclasses slot of the class union. In order for this technique to work, the internal computations for expressions such as `extends(class1, class2)` work differently for class unions than for regular classes; specifically, they test whether any class is in common between the superclasses of `class1` and the subclasses of `class2`.

The different behavior for class unions is made possible because the class definition object for class unions has itself a special class, "ClassUnionRepresentation", an extension of class `classRepresentation`.

## Examples

```
a class for either numeric or logical data
setClassUnion("maybeNumber", c("numeric", "logical"))

use the union as the data part of another class
setClass("withId", representation("maybeNumber", id = "character"))

w1 <- new("withId", 1:10, id = "test 1")
w2 <- new("withId", sqrt(w1)%%1 < .01, id = "Perfect squares")
```

```

add class "complex" to the union "maybeNumber"
setIs("complex", "maybeNumber")

w3 <- new("withId", complex(real = 1:10, imaginary = sqrt(1:10)))

a class union containing the existing class union "OptionalFunction"
setClassUnion("maybeCode",
 c("expression", "language", "OptionalFunction"))

is(quote(sqrt(1:10)), "maybeCode") ## TRUE

```

**setGeneric***Define a New Generic Function***Description**

Create a new generic function of the given name, that is, a function that dispatches methods according to the classes of the arguments, from among the formal methods defined for this function.

**Usage**

```

setGeneric(name, def= , group=list(), valueClass=character(),
 where= , package= , signature= , useAsDefault= ,
 genericFunction= , simpleInheritanceOnly =)

setGroupGeneric(name, def= , group=list(), valueClass=character(),
 knownMembers=list(), package= , where=)

```

**Arguments**

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>name</b>  | The character string name of the generic function. The simplest (and recommended) call, <code>setGeneric(name)</code> , looks for a function with this name and creates a corresponding generic function, if the function found was not generic. In the latter case, the existing function becomes the default method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>def</b>   | An optional function object, defining the generic. Don't supply this argument if you want to turn an existing non-generic function into a generic. In this case, you usually want to use the simple call with one argument.<br><br>Do supply <code>def</code> if there is no current function of this name or for some reason you do not want to use that function to define the generic. In that case, the formal arguments and default values for the generic are taken from <code>def</code> . In most cases, the body of <code>def</code> will then define the default method, as the existing function did in the one-argument call.<br><br>If you want to create a new generic function with <i>no</i> default method, then <code>def</code> should be only a call to <code>standardGeneric</code> with the same character string as <code>name</code> . |
| <b>group</b> | Optionally, a character string giving the name of the group generic function to which this function belongs. See <a href="#">Methods</a> for details of group generic functions in method selection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>valueClass</code>            | An optional character vector of one or more class names. The value returned by the generic function must have (or extend) this class, or one of the classes; otherwise, an error is generated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>package</code>               | The name of the package with which this function is associated. Usually determined automatically (as the package containing the non-generic version if there is one, or else the package where this generic is to be saved).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>where</code>                 | Where to store the resulting initial methods definition, and possibly the generic function; by default, stored into the top-level environment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>signature</code>             | Optionally, the vector of names, from among the formal arguments to the function, that can appear in the signature of methods for this function, in calls to <code>setMethod</code> . If ... is one of the formal arguments, it is treated specially. Starting with version 2.8.0 of R, ... may be signature of the generic function. Methods will then be selected if their signature matches all the ... arguments. See the documentation for topic <code>dotsMethods</code> for details. In the present version, it is not possible to mix ... and other arguments in the signature (this restriction may be lifted in later versions).<br><br>By default, the signature is inferred from the implicit generic function corresponding to a non-generic function. If no implicit generic function has been defined, the default is all the formal arguments except ..., in the order they appear in the function definition. In the case that ... is the only formal argument, that is also the default signature. To use ... as the signature in a function that has any other arguments, you must supply the signature argument explicitly. See the “Implicit Generic” section below for more details. |
| <code>useAsDefault</code>          | Override the usual choice of default argument. Argument <code>useAsDefault</code> can be supplied, either as a function to use for the default, or as a logical value. This argument is now rarely needed. See the section on details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>simpleInheritanceOnly</code> | Supply this argument as TRUE to require that methods selected be inherited through simple inheritance only; that is, from superclasses specified in the <code>contains=</code> argument to <code>setClass</code> , or by simple inheritance to a class union or other virtual class. Generic functions should require simple inheritance if they need to be assured that they get the complete original object, not one that has been transformed. Examples of functions requiring simple inheritance are <code>initialize</code> , because by definition it must return an object from the same class as its argument, and <code>show</code> , because it claims to give a full description of the object provided as its argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>genericFunction</code>       | Don't use; for (possible) internal use only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>knownMembers</code>          | (For <code>setGroupGeneric</code> only.) The names of functions that are known to be members of this group. This information is used to reset cached definitions of the member generics when information about the group generic is changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Value

The `setGeneric` function exists for its side effect: saving the generic function to allow methods to be specified later. It returns `name`.

## Basic Use

The `setGeneric` function is called to initialize a generic function as preparation for defining some methods for that function.

The simplest and most common situation is that name is already an ordinary non-generic non-primitive function, and you now want to turn this function into a generic. In this case you will most often supply only name, for example:

```
setGeneric("colSums")
```

There must be an existing function of this name, on some attached package (in this case package "base"). A generic version of this function will be created in the current package (or in the global environment if the call to `setGeneric()` is from an ordinary source file or is entered on the command line). The existing function becomes the default method, and the package slot of the new generic function is set to the location of the original function ("base" in the example). It's an important feature that the same generic function definition is created each time, depending in the example only on the definition of `print` and where it is found. The signature of the generic function, defining which of the formal arguments can be used in specifying methods, is set by default to all the formal arguments except ....

Note that calling `setGeneric()` in this form is not strictly necessary before calling `setMethod()` for the same function. If the function specified in the call to `setMethod` is not generic, `setMethod` will execute the call to `setGeneric` itself. Declaring explicitly that you want the function to be generic can be considered better programming style; the only difference in the result, however, is that not doing so produces a message noting the creation of the generic function.

You cannot (and never need to) create an explicit generic version of the primitive functions in the base package. Those which can be treated as generic functions have methods selected and dispatched from the internal C code, to satisfy concerns for efficiency, and the others cannot be made generic. See the section on Primitive Functions below.

The description above is the effect when the package that owns the non-generic function has not created an implicit generic version. Otherwise, it is this implicit generic function that is used. See the section on Implicit Generic Functions below. Either way, the essential result is that the *same* version of the generic function will be created each time.

The second common use of `setGeneric()` is to create a new generic function, unrelated to any existing function, and frequently having no default method. In this case, you need to supply a skeleton of the function definition, to define the arguments for the function. The body of a generic function is usually a standard form, `standardGeneric(name)` where name is the quoted name of the generic function. When calling `setGeneric` in this form, you would normally supply the `def` argument as a function of this form. See the second and third examples below.

The `useAsDefault` argument controls the default method for the new generic. If not told otherwise, `setGeneric` will try to find a non-generic version of the function to use as a default. So, if you do have a suitable default method, it is often simpler to first set this up as a non-generic function, and then use the one-argument call to `setGeneric` at the beginning of this section. See the first example in the Examples section below.

If you *don't* want the existing function to be taken as default, supply the argument `useAsDefault`. That argument can be the function you want to be the default method, or `FALSE` to force no default (i.e., to cause an error if there is no direct or inherited method selected for a call to the function).

## Details

The great majority of calls to `setGeneric()` should either have one argument to ensure that an existing function can have methods, or arguments `name` and `def` to create a new generic function and optionally a default method. If that's not what you plan to do, read on.

If you want to change the behavior of an existing function (typically, one in another package) when you create a generic version, you must supply arguments to `setGeneric` correspondingly. Whatever changes are made, the new generic function will be assigned with a package slot set to the *current* package, not the one in which the non-generic version of the function is found. This step is required

because the version you are creating is no longer the same as that implied by the function in the other package. A message will be printed to indicate that this has taken place and noting one of the differences between the two functions. It tends to be a bad idea, because the two versions are now competing for methods, with many chances for mistakes in programming.

The body of a generic function usually does nothing except for dispatching methods by a call to `standardGeneric`. Under some circumstances you might just want to do some additional computation in the generic function itself. As long as your function eventually calls `standardGeneric` that is permissible (though perhaps not a good idea, in that it may make the behavior of your function less easy to understand). If your explicit definition of the generic function does *not* call `standardGeneric` you are in trouble, because none of the methods for the function will ever be dispatched.

By default, the generic function can return any object. If `valueClass` is supplied, it should be a vector of class names; the value returned by a method is then required to satisfy `is(object, Class)` for one of the specified classes. An empty (i.e., zero length) vector of classes means anything is allowed. Note that more complicated requirements on the result can be specified explicitly, by defining a non-standard generic function.

The `setGroupGeneric` function behaves like `setGeneric` except that it constructs a group generic function, differing in two ways from an ordinary generic function. First, this function cannot be called directly, and the body of the function created will contain a stop call with this information. Second, the group generic function contains information about the known members of the group, used to keep the members up to date when the group definition changes, through changes in the search list or direct specification of methods, etc.

## **Implicit Generic Functions**

Saying that a non-generic function “is converted to a generic” is more precisely state that the function is converted to the corresponding *implicit* generic function. If no special action has been taken, any function corresponds implicitly to a generic function with the same arguments, in which all arguments other than `...` can be used. The signature of this generic function is the vector of formal arguments, in order, except for `...`.

The source code for a package can define an implicit generic function version of any function in that package (see `implicitGeneric` for the mechanism). You can not, generally, define an implicit generic function in someone else’s package. The usual reason for defining an implicit generic is to prevent certain arguments from appearing in the signature, which you must do if you want the arguments to be used literally or if you want to enforce lazy evaluation for any reason. An implicit generic can also contain some methods that you want to be predefined; in fact, the implicit generic can be any generic version of the non-generic function. The implicit generic mechanism can also be used to prohibit a generic version (see `prohibitGeneric`).

Whether defined or inferred automatically, the implicit generic will be compared with the generic function that `setGeneric` creates, when the implicit generic is in another package. If the two functions are identical, then the package slot of the created generic will have the name of the package containing the implicit generic. Otherwise, the slot will be the name of the package in which the generic is assigned.

The purpose of this rule is to ensure that all methods defined for a particular combination of generic function and package names correspond to a single, consistent version of the generic function. Calling `setGeneric` with only `name` and possibly `package` as arguments guarantees getting the implicit generic version, if one exists.

Including any of the other arguments can force a new, local version of the generic function. If you don’t want to create a new version, don’t use the extra arguments.

## Generic Functions and Primitive Functions

A number of the basic R functions are specially implemented as primitive functions, to be evaluated directly in the underlying C code rather than by evaluating an R language definition. Most have implicit generics (see [implicitGeneric](#)), and become generic as soon as methods (including group methods) are defined on them. Others cannot be made generic.

Even when methods are defined for such functions, the generic version is not visible on the search list, in order that the C version continues to be called. Method selection will be initiated in the C code. Note, however, that the result is to restrict methods for primitive functions to signatures in which at least one of the classes in the signature is a formal S4 class.

To see the generic version of a primitive function, use [getGeneric\(name\)](#). The function [isGeneric](#) will tell you whether methods are defined for the function in the current session.

Note that S4 methods can only be set on those primitives which are ‘[internal generic](#)’, plus %\*%.

[Methods](#) and the links there for a general discussion, [dotsMethods](#) for methods that dispatch on “...”, and [setMethod](#) for method definitions.

## Examples

```
create a new generic function, with a default method
setGeneric("props", function(object) attributes(object))

A new generic function with no default method
setGeneric("increment",
 function(object, step, ...)
 standardGeneric("increment")
)

A non-standard generic function. It insists that the methods
return a non-empty character vector (a stronger requirement than
valueClass = "character" in the call to setGeneric)

setGeneric("authorNames",
 function(text) {
 value <- standardGeneric("authorNames")
 if(!(value, "character") && any(nchar(value)>0)))
 stop("authorNames methods must return non-empty strings")
 value
})

An example of group generic methods, using the class
"track"; see the documentation of \link{setClass} for its definition
```

```

define a method for the Arith group

setMethod("Arith", c("track", "numeric"),
 function(e1, e2) {
 e1@y <- callGeneric(e1@y , e2)
 e1
 })

setMethod("Arith", c("numeric", "track"),
 function(e1, e2) {
 e2@y <- callGeneric(e1, e2@y)
 e2
 })

now arithmetic operators will dispatch methods:

t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))

t1 - 100
1/t1

```

**setLoadActions***Set Actions For Package Loading***Description**

These functions provide a mechanism for packages to specify computations to be done during the loading of the package namespace. Such actions are a flexible way to provide information only available at load time (such as locations in a dynamically linked library).

A call to `setLoadAction()` or `setLoadActions()` specifies one or more functions to be called when the corresponding package is loaded, with the `...` argument names being used as identifying names for the actions.

`getLoadActions` reports the currently defined load actions, given a package's namespace as its argument.

`hasLoadAction` returns TRUE if a load action corresponding to the given name has previously been set for the `where` namespace.

`evalOnLoad()` and `evalqOnLoad()` schedule a specific expression for evaluation at load time.

**Usage**

```

setLoadAction(action, aname=, where=)

setLoadActions(..., .where=)

getLoadActions(where=)

hasLoadAction(aname, where=)

evalOnLoad(expr, where=, aname=)

```

```
evalqOnLoad(expr, where=, aname=)
```

## Arguments

|               |                                                                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| action, ...   | functions of one or more arguments, to be called when this package is loaded. The functions will be called with one argument (the package namespace) so all following arguments must have default values.<br>If the elements of ... are named, these names will be used for the corresponding load metadata. |
| where, .where | the namespace of the package for which the list of load actions are defined. This argument is normally omitted if the call comes from the source code for the package itself, but will be needed if a package supplies load actions for another package.                                                     |
| aname         | the name for the action. If an action is set without supplying a name, the default uses the position in the sequence of actions specified ("." 1", etc.).                                                                                                                                                    |
| expr          | an expression to be evaluated in a load action in environment where. In the case of evalqOnLoad(), the expression is interpreted literally, in that of evalOnLoad() it must be precomputed, typically as an object of type "language".                                                                       |

## Details

The evalOnLoad() and evalqOnLoad() functions are for convenience. They construct a function to evaluate the expression and call setLoadAction() to schedule a call to that function.

Each of the functions supplied as an argument to setLoadAction() or setLoadActions() is saved as metadata in the namespace, typically that of the package containing the call to setLoadActions(). When this package's namespace is loaded, each of these functions will be called. Action functions are called in the order they are supplied to setLoadActions(). The objects assigned have metadata names constructed from the names supplied in the call; unnamed arguments are taken to be named by their position in the list of actions ("." 1", etc.).

Multiple calls to setLoadAction() or setLoadActions() can be used in a package's code; the actions will be scheduled after any previously specified, except if the name given to setLoadAction() is that of an existing action. In typical applications, setLoadActions() is more convenient when calling from the package's own code to set several actions. Calls to setLoadAction() are more convenient if the action name is to be constructed, which is more typical when one package constructs load actions for another package.

Actions can be revised by assigning with the same name, actual or constructed, in a subsequent call. The replacement must still be a valid function, but can of course do nothing if the intention was to remove a previously specified action.

The functions must have at least one argument. They will be called with one argument, the namespace of the package. The functions will be called at the end of processing of S4 metadata, after dynamically linking any libraries, the call to .onLoad(), if any, and caching method and class definitions, but before the namespace is sealed.

Functions may therefore assign or modify objects in the namespace supplied as the argument in the call. The mechanism allows packages to save information not available until load time, such as values obtained from a dynamically linked library.

Load actions should be contrasted with user load hooks supplied by [setHook\(\)](#). User hooks are generally provided from outside the package and are run after the namespace has been sealed. Load

actions are part of the package code, and the list of actions is normally established when the package is installed.

Load actions can be supplied directly in the source code for a package. It is also possible and useful to provide facilities in one package to create load actions in another package. The software needs to be careful to assign the action functions in the correct environment, namely the namespace of the target package.

### **Value**

`setLoadAction()` and `setLoadActions()` are called for their side effect and return no useful value.

`getLoadActions()` returns a named list of the actions in the supplied namespace.

`hasLoadAction()` returns TRUE if the specified action name appears in the actions for this package.

### **Examples**

```
Not run:
in the code for some package

... somewhere else
setLoadActions(function(attach)
 cat(c("Loaded", "Unloaded")[attach], "at", Sys.time(), "\n"),
 setCount = function(ns) assign("myCount", 1, envir = ns),
 function(ns) assign("myPointer", getMyExternalPointer(), envir = ns))
 ... somewhere later
if(countShouldBe0)
 setLoadAction(function(ns) assign("myCount", 0, envir = ns), "setCount")

End(Not run)
```

## **setMethod**

### *Create and Save a Method*

### **Description**

Create and save a formal method for a given function and list of classes.

### **Usage**

```
setMethod(f, signature=character(), definition,
 where = topenv(parent.frame()),
 valueClass = NULL, sealed = FALSE)

removeMethod(f, signature, where)
```

### **Arguments**

- |                        |                                                                                                                                                                                                                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>         | A generic function or the character-string name of the function.                                                                                                                                                                                                                   |
| <code>signature</code> | A match of formal argument names for <code>f</code> with the character-string names of corresponding classes. See the details below; however, if the signature is not trivial, you should use <a href="#">method.skeleton</a> to generate a valid call to <code>setMethod</code> . |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| definition | A function definition, which will become the method called when the arguments in a call to <code>f</code> match the classes in <code>signature</code> , directly or through inheritance.                                                                                                                                                                                                                                                                                        |
| where      | the environment in which to store the definition of the method. For <code>setMethod</code> , it is recommended to omit this argument and to include the call in source code that is evaluated at the top level; that is, either in an R session by something equivalent to a call to <code>source</code> , or as part of the R source code for a package. For <code>removeMethod</code> , the default is the location of the (first) instance of the method for this signature. |
| valueClass | Obsolete and unused, but see the same argument for <code>setGeneric</code> .                                                                                                                                                                                                                                                                                                                                                                                                    |
| sealed     | If <code>TRUE</code> , the method so defined cannot be redefined by another call to <code>setMethod</code> (although it can be removed and then re-assigned).                                                                                                                                                                                                                                                                                                                   |

## Details

The call to `setMethod` stores the supplied method definition in the metadata table for this generic function in the environment, typically the global environment or the namespace of a package. In the case of a package, the table object becomes part of the namespace or environment of the package. When the package is loaded into a later session, the methods will be merged into the table of methods in the corresponding generic function object.

Generic functions are referenced by the combination of the function name and the package name; for example, the function "show" from the package "methods". Metadata for methods is identified by the two strings; in particular, the generic function object itself has slots containing its name and its package name. The package name of a generic is set according to the package from which it originally comes; in particular, and frequently, the package where a non-generic version of the function originated. For example, generic functions for all the functions in package `base` will have "base" as the package name, although none of them is an S4 generic on that package. These include most of the base functions that are primitives, rather than true functions; see the section on primitive functions in the documentation for `setGeneric` for details.

Multiple packages can have methods for the same generic function; that is, for the same combination of generic function name and package name. Even though the methods are stored in separate tables in separate environments, loading the corresponding packages adds the methods to the table in the generic function itself, for the duration of the session.

The class names in the signature can be any formal class, including basic classes such as "numeric", "character", and "matrix". Two additional special class names can appear: "ANY", meaning that this argument can have any class at all; and "missing", meaning that this argument *must not* appear in the call in order to match this signature. Don't confuse these two: if an argument isn't mentioned in a signature, it corresponds implicitly to class "ANY", not to "missing". See the example below. Old-style ('S3') classes can also be used, if you need compatibility with these, but you should definitely declare these classes by calling `setOldClass` if you want S3-style inheritance to work.

Method definitions can have default expressions for arguments, but a current limitation is that the generic function must have *some* default expression for the same argument in order for the method's defaults to be used. If so, and if the corresponding argument is missing in the call to the generic function, the default expression in the method is used. If the method definition has no default for the argument, then the expression supplied in the definition of the generic function itself is used, but note that this expression will be evaluated using the enclosing environment of the method, not of the generic function. Note also that specifying class "missing" in the signature does not require any default expressions, and method selection does not evaluate default expressions. All actual (non-missing) arguments in the signature of the generic function will be evaluated when a method is selected—when the call to `standardGeneric(f)` occurs.

It is possible to have some differences between the formal arguments to a method supplied to `setMethod` and those of the generic. Roughly, if the generic has ... as one of its arguments, then

the method may have extra formal arguments, which will be matched from the arguments matching ... in the call to f. (What actually happens is that a local function is created inside the method, with the modified formal arguments, and the method is re-defined to call that local function.)

Method dispatch tries to match the class of the actual arguments in a call to the available methods collected for f. If there is a method defined for the exact same classes as in this call, that method is used. Otherwise, all possible signatures are considered corresponding to the actual classes or to superclasses of the actual classes (including "ANY"). The method having the least distance from the actual classes is chosen; if more than one method has minimal distance, one is chosen (the lexicographically first in terms of superclasses) but a warning is issued. All inherited methods chosen are stored in another table, so that the inheritance calculations only need to be done once per session per sequence of actual classes. See [Methods](#) for more details.

The function `removeMethod` removes the specified method from the metadata table in the corresponding environment. It's not a function that is used much, since one normally wants to redefine a method rather than leave no definition.

### Value

These functions exist for their side-effect, in setting or removing a method in the object defining methods for the specified generic.

The value returned by `removeMethod` is TRUE if a method was found to be removed.

[Methods](#) and the links there for a general discussion, [dotsMethods](#) for methods that dispatch on "...", and [setGeneric](#) for generic functions.

### Examples

```
require(graphics)
methods for plotting track objects (see the example for \link{setClass})
##
First, with only one object as argument:
setMethod("plot", signature(x="track", y="missing"),
 function(x, y, ...) plot(slot(x, "x"), slot(x, "y"), ...))
##
Second, plot the data from the track on the y-axis against anything
as the x data.
setMethod("plot", signature(y = "track"),
 function(x, y, ...) plot(x, slot(y, "y"), ...))
##
and similarly with the track on the x-axis (using the short form of
specification for signatures)
setMethod("plot", "track",
 function(x, y, ...) plot(slot(x, "y"), y, ...))
```

```

)
t1 <- new("track", x=1:20, y=(1:20)^2)
tc1 <- new("trackCurve", t1)
slot(tc1, "smooth") <- smooth.spline(slot(tc1, "x"), slot(tc1, "y"))$y #$
plot(t1)
plot(qnorm(ppoints(20)), t1)
An example of inherited methods, and of conforming method arguments
(note the dotCurve argument in the method, which will be pulled out
of ... in the generic.
setMethod("plot", c("trackCurve", "missing"),
function(x, y, dotCurve = FALSE, ...) {
 plot(as(x, "track"))
 if(length(slot(x, "smooth")) > 0))
 lines(slot(x, "x"), slot(x, "smooth"),
 lty = if(dotCurve) 2 else 1)
})
the plot of tc1 alone has an added curve; other uses of tc1
are treated as if it were a "track" object.
plot(tc1, dotCurve = TRUE)
plot(qnorm(ppoints(20)), tc1)

defining methods for a special function.
Although "[" and "length" are not ordinary functions
methods can be defined for them.
setMethod("[", "track",
function(x, i, j, ..., drop) {
 x@x <- x@x[i]; x@y <- x@y[i]
 x
})
plot(t1[1:15])

setMethod("length", "track", function(x)length(x@y))
length(t1)

methods can be defined for missing arguments as well
setGeneric("summary") ## make the function into a generic

A method for summary()
The method definition can include the arguments, but
if they're omitted, class "missing" is assumed.

setMethod("summary", "missing", function() "<No Object>")

```

## Description

Register an old-style (a.k.a. ‘S3’) class as a formally defined class. The `Classes` argument is the character vector used as the `class` attribute; in particular, if there is more than one string, old-style class inheritance is mimicked. Registering via `setOldClass` allows S3 classes to appear in method signatures, as a slot in an S4 class, or as a superclass of an S4 class.

**Usage**

```
setOldClass(Classes, prototype, where, test = FALSE, S4Class)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Classes   | A character vector, giving the names for S3 classes, as they would appear on the right side of an assignment of the <code>class</code> attribute in S3 computations.<br>In addition to S3 classes, an object type or other valid data part can be specified, if the S3 class is known to require its data to be of that form.                                                 |
| prototype | An optional object to use as the prototype. This should be provided as the default S3 object for the class. If omitted, the S4 class created to register the S3 class is <code>VIRTUAL</code> . See the details.                                                                                                                                                              |
| where     | Where to store the class definitions, the global or top-level environment by default. (When either function is called in the source for a package, the class definitions will be included in the package's environment by default.)                                                                                                                                           |
| test      | flag, if <code>TRUE</code> , arrange to test inheritance explicitly for each object, needed if the S3 class can have a different set of class strings, with the same first string. This is a different mechanism in implementation and should be specified separately for each pair of classes that have an optional inheritance. See the 'Details'.                          |
| S4Class   | optionally, the class definition or the class name of an S4 class. The new class will have all the slots and other properties of this class, plus its S3 inheritance as defined by the <code>Classses</code> argument. Arguments <code>prototype</code> and <code>test</code> must not be supplied in this case. See the section on "S3 classes with known attributes" below. |

**Details**

Each of the names will be defined as an S4 class, extending the remaining classes in `Classes`, and the class `oldClass`, which is the 'root' of all old-style classes. S3 classes have no formal definition, and therefore no formally defined slots. If a `prototype` argument is supplied in the call to `setOldClass()`, objects from the class can be generated, by a call to `new`; however, this usually not as relevant as generating objects from subclasses (see the section on extending S3 classes below). If a `prototype` is not provided, the class will be created as a virtual S4 class. The main disadvantage is that the `prototype` object in an S4 class that uses this class as a slot will have a `NULL` object in that slot, which can sometimes lead to confusion.

Beginning with version 2.8.0 of R, support is provided for using a (registered) S3 class as a superclass of a new S4 class. See the section on extending S3 classes below, and the examples.

See [Methods](#) for the details of method dispatch and inheritance.

Some S3 classes cannot be represented as an ordinary combination of S4 classes and superclasses, because objects from the S3 class can have a variable set of strings in the class. It is still possible to register such classes as S4 classes, but now the inheritance has to be verified for each object, and you must call `setOldClass` with argument `test=TRUE` once for each superclass.

For example, ordered factors *always* have the S3 class `c("ordered", "factor")`. This is proper behavior, and maps simply into two S4 classes, with "ordered" extending "factor".

But objects whose class attribute has "POSIXt" as the first string may have either (or neither) of "POSIXct" or "POSIXlt" as the second string. This behavior can be mapped into S4 classes but now to evaluate `is(x, "POSIXlt")`, for example, requires checking the S3 class attribute on each object. Supplying the `test=TRUE` argument to `setOldClass` causes an explicit test to be included in the class definitions. It's never wrong to have this test, but since it adds significant overhead to

methods defined for the inherited classes, you should only supply this argument if it's known that object-specific tests are needed.

The list `.OldClassesList` contains the old-style classes that are defined by the methods package. Each element of the list is a character vector, with multiple strings if inheritance is included. Each element of the list was passed to `setOldClass` when creating the **methods** package; therefore, these classes can be used in `setMethod` calls, with the inheritance as implied by the list.

### Extending S3 classes

A call to `setOldClass` creates formal classes corresponding to S3 classes, allows these to be used as slots in other classes or in a signature in `setMethod`, and mimics the S3 inheritance.

In documentation for the initial implementation of S4 classes in R, users were warned against defining S4 classes that contained S3 classes, even if those had been registered. The warning was based mainly on two points. 1: The S3 behavior of the objects would fail because the S3 class would not be visible, for example, when S3 methods are dispatched. 2: Because S3 classes have no formal definition, nothing can be asserted in general about the S3 part of an object from such a class. (The warning was repeated as recently as the first reference below.)

Nevertheless, defining S4 classes to contain an S3 class and extend its behavior is attractive in many applications. The alternative is to be stuck with S3 programming, without the flexibility and security of formal class and method definitions.

Beginning with version 2.8.0, R provides support for extending registered S3 classes; that is, for new classes defined by a call to `setClass` in which the `contains=` argument includes an S3 class. See the examples below. The support is aimed primarily at providing the S3 class information for all classes that extend class `oldClass`, in particular by ensuring that all objects from such classes contain the S3 class in a special slot.

There are three different ways to indicate an extension to an existing S3 class: `setOldClass()`, `setClass()` and `setIs()`. In most cases, calling `setOldClass` is the best approach, but the alternatives may be preferred in the special circumstances described below.

Suppose "A" is any class extending "oldClass". then

```
setOldClass(c("B", "A"))
```

creates a new class "B" whose S3 class concatenates "B" with `S3Class("A")`. The new class is a virtual class. If "A" was defined with known attribute/slots, then "B" has these slots also; therefore, you must believe that the corresponding S3 objects from class "B" do indeed have the claimed attributes. Notice that you can supply an S4 definition for the new class to specify additional attributes (as described in the next section.) The first alternative call produces a non-virtual class.

```
setClass("B", contains = "A")
```

This creates a non-virtual class with the same slots and superclasses as class "A". However, class "B" is not included in the S3 class slot of the new class, unless you provide it explicitly in the prototype.

```
setClass("B"); setIs("B", "A",)
```

This creates a virtual class that extends "A", but does not contain the slots of "A". The additional arguments to `setIs` should provide a coerce and replacement method. In order for the new class to inherit S3 methods, the coerce method must ensure that the class "A" object produced has a suitable S3 class. The only likely reason to prefer this third approach is that class "B" is not consistent with known attributes in class "A".

Beginning with version 2.9.0 of R, objects from a class extending an S3 class will be converted to the corresponding S3 class when being passed to an S3 method defined for that class (that is, for one of the strings in the S3 class attribute). This is intended to ensure, as far as possible, that such methods will work if they work for ordinary S3 objects. See [Classes](#) for details.

### S3 Classes with known attributes

A further specification of an S3 class can be made *if* the class is guaranteed to have some attributes of known class (where as with slots, “known” means that the attribute is an object of a specified class, or a subclass of that class).

In this case, the call to `setOldClass()` can supply an S4 class definition representing the known structure. Since S4 slots are implemented as attributes (largely for just this reason), the known attributes can be specified in the representation of the S4 class. The usual technique will be to create an S4 class with the desired structure, and then supply the class name or definition as the argument `S4Class` to `setOldClass()`.

See the definition of class “`ts`” in the examples below. The call to `setClass` to create the S4 class can use the same class name, as here, so long as the class definition is not sealed. In the example, we define “`ts`” as a vector structure with a numeric slot for “`tsp`”. The validity of this definition relies on an assertion that all the S3 code for this class is consistent with that definition; specifically, that all “`ts`” objects will behave as vector structures and will have a numeric “`tsp`” attribute. We believe this to be true of all the base code in R, but as always with S3 classes, no guarantee is possible.

The S4 class definition can have virtual superclasses (as in the “`ts`” case) if the S3 class is asserted to behave consistently with these (in the example, time-series objects are asserted to be consistent with the `structure` class).

For another example, look at the S4 class definition for “`data.frame`”.

Be warned that failures of the S3 class to live up to its asserted behavior will usually go uncorrected, since S3 classes inherently have no definition, and the resulting invalid S4 objects can cause all sorts of grief. Many S3 classes are not candidates for known slots, either because the presence or class of the attributes are not guaranteed (e.g., `dimnames` in arrays, although these are not even S3 classes), or because the class uses named components of a list rather than attributes (e.g., “`lm`”). An attribute that is sometimes missing cannot be represented as a slot, not even by pretending that it is present with class “`NULL`”, because attributes unlike slots can not have value `NULL`.

One irregularity that is usually tolerated, however, is to optionally add other attributes to those guaranteed to exist (for example, “`terms`” in “`data.frame`” objects returned by `model.frame`). As of version 2.8.0, validity checks by `validObject` ignore extra attributes; even if this check is tightened in the future, classes extending S3 classes would likely be exempted because extra attributes are so common.

`setClass`, `setMethod`

## Examples

```
require(stats)
setOldClass(c("m1m", "1m"))
setGeneric("dfResidual", function(model)standardGeneric("dfResidual"))
setMethod("dfResidual", "1m", function(model)model$df.residual)

dfResidual will work on m1m objects as well as lm objects
```

```

myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData)

showClass("data.frame")# to see the predefined S4 "oldClass"

two examples extending S3 class "lm", class "xlm" directly
and "ylm" indirectly
setClass("xlm", representation(eps = "numeric"), contains = "lm")
setClass("ylm", representation(header = "character"), contains = "xlm")
ym1 = new("ylm", myLm, header = "Example", eps = 0.)
for more examples, see ?\link{S3Class}.

utils::str(.OldClassesList)

Examples of S3 classes with guaranteed attributes
an S3 class "stamped" with a vector and a "date" attribute
Here is a generator function and an S3 print method.
NOTE: its essential that the generator checks the attribute classes
stamped <- function(x, date = Sys.time()) {
 if(!inherits(date, "POSIXt"))
 stop("bad date argument")
 if(!is.vector(x))
 stop("x must be a vector")
 attr(x, "date") <- date
 class(x) <- "stamped"
 x
}

print.stamped <- function(x, ...) {
 print(as.vector(x))
 cat("Date: ", format(attr(x,"date")), "\n")
}

Now, an S4 class with the same structure:
setClass("stamped4", contains = "vector", representation(date = "POSIXt"))

We can use the S4 class to register "stamped", with its attributes:
setOldClass("stamped", S4Class = "stamped4")
selectMethod("show", "stamped")
and then remove "stamped4" to clean up
removeClass("stamped4")

someLetters <- stamped(sample(letters, 10),
 ISOdatetime(2008, 10, 15, 12, 0, 0))

st <- new("stamped", someLetters)
st
show() method prints the objects class, then calls the S3 print method.

stopifnot(identical(S3Part(st, TRUE), someLetters))

creating the S4 object directly from its data part and slots
new("stamped", 1:10, date = ISOdatetime(1976, 5, 5, 15, 10, 0))

Not run:

```

```
The code in R that defines "ts" as an S4 class
setClass("ts", contains = "structure",
 representation(tsp = "numeric"),
 prototype(NA, tsp = rep(1,3)))
prototype to be a legal S3 time-series
and now registers it as an S3 class
setOldClass("ts", S4Class = "ts", where = envir)

End(Not run)
```

**show***Show an Object***Description**

Display the object, by printing, plotting or whatever suits its class. This function exists to be specialized by methods. The default method calls [showDefault](#).

Formal methods for show will usually be invoked for automatic printing (see the details).

**Usage**

```
show(object)
```

**Arguments**

|        |              |
|--------|--------------|
| object | Any R object |
|--------|--------------|

**Details**

Objects from an S4 class (a class defined by a call to [setClass](#)) will be displayed automatically if by a call to show. S4 objects that occur as attributes of S3 objects will also be displayed in this form; conversely, S3 objects encountered as slots in S4 objects will be printed using the S3 convention, as if by a call to [print](#).

Methods defined for show will only be inherited by simple inheritance, since otherwise the method would not receive the complete, original object, with misleading results. See the `simpleInheritanceOnly` argument to [setGeneric](#) and the discussion in [setIs](#) for the general concept.

**Value**

`show` returns an invisible NULL.

**See Also**

[showMethods](#) prints all the methods for one or more functions.

## Examples

```

following the example shown in the setMethod documentation ...
setClass("track",
 representation(x="numeric", y="numeric"))
setClass("trackCurve",
 representation("track", smooth = "numeric"))

t1 <- new("track", x=1:20, y=(1:20)^2)

tc1 <- new("trackCurve", t1)

setMethod("show", "track",
 function(object)print(rbind(x = object@x, y=object@y))
)
The method will now be used for automatic printing of t1

t1

Not run: [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10] [,11] [,12]
x 1 2 3 4 5 6 7 8 9 10 11 12
y 1 4 9 16 25 36 49 64 81 100 121 144
[,13] [,14] [,15] [,16] [,17] [,18] [,19] [,20]
x 13 14 15 16 17 18 19 20
y 169 196 225 256 289 324 361 400

End(Not run)
and also for tc1, an object of a class that extends "track"
tc1

Not run: [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10] [,11] [,12]
x 1 2 3 4 5 6 7 8 9 10 11 12
y 1 4 9 16 25 36 49 64 81 100 121 144
[,13] [,14] [,15] [,16] [,17] [,18] [,19] [,20]
x 13 14 15 16 17 18 19 20
y 169 196 225 256 289 324 361 400

End(Not run)

```

showMethods

*Show all the methods for the specified function(s)*

## Description

Show a summary of the methods for one or more generic functions, possibly restricted to those involving specified classes.

## Usage

```
showMethods(f = character(), where = topenv(parent.frame()),
 classes = NULL, includeDefs = FALSE,
 inherited = !includeDefs,
 showEmpty, printTo = stdout(), fdef)
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>           | one or more function names. If omitted, all functions will be shown that match the other arguments.<br>The argument can also be an expression that evaluates to a single generic function, in which case argument <code>fdef</code> is ignored. Providing an expression for the function allows examination of hidden or anonymous functions; see the example for <code>isDiagonal()</code> .          |
| <code>where</code>       | Where to find the generic function, if not supplied as an argument. When <code>f</code> is missing, or length 0, this also determines which generic functions to examine. If <code>where</code> is supplied, only the generic functions returned by <code>getGenerics(where)</code> are eligible for printing. If <code>where</code> is also missing, all the cached generic functions are considered. |
| <code>classes</code>     | If argument <code>classes</code> is supplied, it is a vector of class names that restricts the displayed results to those methods whose signatures include one or more of those classes.                                                                                                                                                                                                               |
| <code>includeDefs</code> | If <code>includeDefs</code> is TRUE, include the definitions of the individual methods in the printout.                                                                                                                                                                                                                                                                                                |
| <code>inherited</code>   | logical indicating if methods that have been found by inheritance, so far in the session, will be included and marked as inherited. Note that an inherited method will not usually appear until it has been used in this session. See <code>selectMethod</code> if you want to know what method would be dispatched for particular classes of arguments.                                               |
| <code>showEmpty</code>   | logical indicating whether methods with no defined methods matching the other criteria should be shown at all. By default, TRUE if and only if argument <code>f</code> is not missing.                                                                                                                                                                                                                 |
| <code>printTo</code>     | The connection on which the information will be shown; by default, on standard output.                                                                                                                                                                                                                                                                                                                 |
| <code>fdef</code>        | Optionally, the generic function definition to use; if missing, one is found, looking in <code>where</code> if that is specified. See also comment in ‘Details’.                                                                                                                                                                                                                                       |

## Details

The name and package of the generic are followed by the list of signatures for which methods are currently defined, according to the criteria determined by the various arguments. Note that the package refers to the source of the generic function. Individual methods for that generic can come from other packages as well.

When more than one generic function is involved, either as specified or because `f` was missing, the functions are found and `showMethods` is recalled for each, including the generic as the argument `fdef`. In complicated situations, this can avoid some anomalous results.

## Value

If `printTo` is FALSE, the character vector that would have been printed is returned; otherwise the value is the connection or filename, via `invisible`.

## Examples

```
require(graphics)

Assuming the methods for plot
are set up as in the example of help(setMethod),
print (without definitions) the methods that involve class "track":
showMethods("plot", classes = "track")
Not run:
Function "plot":
x = ANY, y = track
x = track, y = missing
x = track, y = ANY

require("Matrix")
showMethods("%*%")# many!
methods(class = "Matrix")# nothing
showMethods(class = "Matrix")# everything
showMethods(Matrix:::isDiagonal) # a non-exported generic

End(Not run)

not.there <- !any("package:stats4" == search())
if(not.there) library(stats4)
showMethods(classes = "mle")
if(not.there) detach("package:stats4")
```

## Description

This class represents the mapping of some of the formal arguments of a function onto the corresponding classes. It is used for two slots in the [MethodDefinition](#) class.

## Objects from the Class

Objects can be created by calls of the form `new("signature", ..., functionDef, ...)`. The `functionDef` argument, if it is supplied as a function object, defines the formal names. The other arguments define the classes. More typically, the objects are created as side effects of defining methods. Either way, note that the classes are expected to be well defined, usually because the corresponding class definitions exist. See the comment on the `package` slot.

**Slots**

.Data: Object of class "character" the class names.  
 names: Object of class "character" the corresponding argument names.  
 package: Object of class "character" the names of the packages corresponding to the class names. The combination of class name and package uniquely defines the class. In principle, the same class name could appear in more than one package, in which case the package information is required for the signature to be well defined.

**Extends**

Class "character", from data part. Class "vector", by class "character".

**Methods**

**initialize** signature(object = "signature"): see the discussion of objects from the class, above.

**See Also**

class [MethodDefinition](#) for the use of this class.

slot

*The Slots in an Object from a Formal Class*

**Description**

These functions return or set information about the individual slots in an object.

**Usage**

```
object@name
object@name <- value

slot(object, name)
slot(object, name, check = TRUE) <- value
.hasSlot(object, name)

slotNames(x)
getSlots(x)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | An object from a formally defined class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| name   | The name of the slot. The operator takes a fixed name, which can be unquoted if it is syntactically a name in the language. A slot name can be any non-empty string, but if the name is not made up of letters, numbers, and ., it needs to be quoted (by backticks or single or double quotes).<br><br>In the case of the <code>slot</code> function, name can be any expression that evaluates to a valid slot in the class definition. Generally, the only reason to use the functional form rather than the simpler operator is <i>because</i> the slot name has to be computed. |

|       |                                                                                                                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | A new value for the named slot. The value must be valid for this slot in this object's class.                                                                                                                                          |
| check | In the replacement version of <code>slot</code> , a flag. If TRUE, check the assigned value for validity as the value of this slot. User's code should not set this to FALSE in normal use, since the resulting object can be invalid. |
| x     | either the name of a class (as character string), or a class definition. If given an argument that is neither a character string nor a class definition, <code>slotNames</code> (only) uses <code>class(x)</code> instead.             |

## Details

The definition of the class specifies all slots directly and indirectly defined for that class. Each slot has a name and an associated class. Extracting a slot returns an object from that class. Setting a slot first coerces the value to the specified slot and then stores it.

Unlike general attributes, slots are not partially matched, and asking for (or trying to set) a slot with an invalid name for that class generates an error.

The `@` extraction operator and `slot` function themselves do no checking against the class definition, simply matching the name in the object itself. The replacement forms do check (except for `slot` in the case `check=FALSE`). So long as slots are set without cheating, the extracted slots will be valid.

Be aware that there are two ways to cheat, both to be avoided but with no guarantees. The obvious way is to assign a slot with `check=FALSE`. Also, slots in R are implemented as attributes, for the sake of some back compatibility. The current implementation does not prevent attributes being assigned, via `attr<-`, and such assignments are not checked for legitimate slot names.

Note that the "`@`" operators for extraction and (since R 3.0.0) replacement are primitive and actually reside in the `base` package.

The replacement versions of "`@`" and `slot()` differ in the computations done to coerce the right side of the assignment to the declared class of the slot. Both verify that the value provided is from a subclass of the declared slot class. The `slot()` version will go on to call the coerce method if there is one, in effect doing the computation `as(value, slotClass, strict = FALSE)`. The "`@`" version just verifies the relation, leaving any coerce to be done later (e.g., when a relevant method is dispatched).

In most uses the result is equivalent, and the "`@`" version saves an extra function call, but if empirical evidence shows that a conversion is needed, either call `as()` before the replacement or use the replacement version of `slot()`.

## Value

The "`@`" operator and the `slot` function extract or replace the formally defined slots for the object. Functions `slotNames` and `getSlots` return respectively the names of the slots and the classes associated with the slots in the specified class definition. Except for its extended interpretation of `x` (above), `slotNames(x)` is just `names(getSlots(x))`.

## Examples

```
setClass("track", representation(x="numeric", y="numeric"))
myTrack <- new("track", x = -4:4, y = exp(-4:4))
slot(myTrack, "x")
slot(myTrack, "y") <- log(slot(myTrack, "y"))
utils::str(myTrack)

getSlots("track") # or
getSlots(getClass("track"))
slotNames(class(myTrack)) # is the same as
slotNames(myTrack)
```

## Description

The virtual class `structure` and classes that extend it are formal classes analogous to S language structures such as arrays and time-series.

## Usage

```
The following class names can appear in method signatures,
as the class in as() and is() expressions, and, except for
the classes commented as VIRTUAL, in calls to new()

"matrix"
"array"
"ts"

"structure" ## VIRTUAL
```

## Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted name of the specific class (e.g., `"matrix"`), and the other arguments, if any, are interpreted as arguments to the corresponding function, e.g., to function `matrix()`. There is no particular advantage over calling those functions directly, unless you are writing software designed to work for multiple classes, perhaps with the class name and the arguments passed in.

Objects created from the classes `"matrix"` and `"array"` are unusual, to put it mildly, and have been for some time. Although they may appear to be objects from these classes, they do not have the internal structure of either an S3 or S4 class object. In particular, they have no `"class"` attribute and are not recognized as objects with classes (that is, both `is.object` and `isS4` will return FALSE for such objects). However, methods (both S4 and S3) can be defined for these pseudo-classes and new classes (both S4 and S3) can inherit from them.

That the objects still behave as if they came from the corresponding class (most of the time, anyway) results from special code recognizing such objects being built into the base code of R. For most purposes, treating the classes in the usual way will work, fortunately. One consequence of the

special treatment is that these two classes *may* be used as the data part of an S4 class; for example, you can get away with `contains = "matrix"` in a call to `setGeneric` to create an S4 class that is a subclass of "matrix". There is no guarantee that everything will work perfectly, but a number of classes have been written in this form successfully.

Note that a class containing "matrix" or "array" will have a `.Data` slot with that class. This is the only use of `.Data` other than as a pseudo-class indicating the type of the object. In this case the type of the object will be the type of the contained matrix or array. See [Classes](#) for a general discussion.

The class "ts" is basically an S3 class that has been registered with S4, using the `setOldClass` mechanism. Versions of R through 2.7.0 treated this class as a pure S4 class, which was in principal a good idea, but in practice did not allow subclasses to be defined and had other intrinsic problems. (For example, setting the "tsp" parameters as a slot often fails because the built-in implementation does not allow the slot to be temporarily inconsistent with the length of the data. Also, the S4 class prevented the correct specification of the S3 inheritance for class "mts".)

Time-series objects, in contrast to matrices and arrays, have a valid S3 class, "ts", registered using an S4-style definition (see the documentation for `setOldClass` in the examples section for an abbreviated listing of how this is done. The S3 inheritance of "mts" in package **stats** is also registered. These classes, as well as "matrix" and "array" should be valid in most examples as superclasses for new S4 class definitions.

All of these classes have special S4 methods for `initialize` that accept the same arguments as the basic generator functions, `matrix`, `array`, and `ts`, in so far as possible. The limitation is that a class that has more than one non-virtual superclass must accept objects from that superclass in the call to `new`; therefore, a such a class (what is called a "mixin" in some languages) uses the default method for `initialize`, with no special arguments.

## Extends

The specific classes all extend class "structure", directly, and class "vector", by class "structure".

## Methods

**coerce** Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, `as(x, "matrix")` calls `as.matrix(x)`. If `strict = TRUE` in the call to `as()`, the method goes on to delete all other slots and attributes other than the `dim` and `dimnames`.

**Ops** Group methods (see, e.g., [S4groupGeneric](#)) are defined for combinations of structures and vectors (including special cases for array and matrix), implementing the concept of vector structures as in the reference. Essentially, structures combined with vectors retain the structure as long as the resulting object has the same length. Structures combined with other structures remove the structure, since there is no automatic way to determine what should happen to the slots defining the structure.

Note that these methods will be activated when a package is loaded containing a class that inherits from any of the structure classes or class "vector".

## See Also

Class [nonStructure](#), which enforces the alternative model, in which all slots are dropped if any math transformation or operation is applied to an object from a class extending one of the basic classes.

## Examples

```
showClass("structure")

explore a bit :
showClass("ts")
(ts0 <- new("ts"))
str(ts0)

showMethods("Ops") # six methods from these classes, but maybe many more
```

**testInheritedMethods** *Test for and Report about Selection of Inherited Methods*

## Description

A set of distinct inherited signatures is generated to test inheritance for all the methods of a specified generic function. If method selection is ambiguous for some of these, a summary of the ambiguities is attached to the returned object. This test should be performed by package authors *before* releasing a package.

## Usage

```
testInheritedMethods(f, signatures, test = TRUE, virtual = FALSE,
 groupMethods = TRUE, where = .GlobalEnv)
```

## Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>f</b>          | a generic function or the character string name of one. By default, all currently defined subclasses of all the method signatures for this generic will be examined. The other arguments are mainly options to modify which inheritance patterns will be examined.                                                                                                  |
| <b>signatures</b> | An optional set of subclass signatures to use instead of the relevant subclasses computed by <code>testInheritedMethods</code> . See the Details for how this is done. This argument might be supplied after a call with <code>test = FALSE</code> , to test selection in batches.                                                                                  |
| <b>test</b>       | optional flag to control whether method selection is actually tested. If <code>FALSE</code> , returns just the list of relevant signatures for subclasses, without calling <a href="#">selectMethod</a> for each signature. If there are a very large number of signatures, you may want to collect the full list and then test them in batches.                    |
| <b>virtual</b>    | should virtual classes be included in the relevant subclasses. Normally not, since only the classes of actual arguments will trigger the inheritance calculation in a call to the generic function. Including virtual classes may be useful if the class has no current non-virtual subclasses but you anticipate your users may define such classes in the future. |

`groupMethods` should methods for the group generic function be included?  
`where` the environment in which to look for class definitions. Nearly always, use the default global environment after attaching all the packages with relevant methods and/or class definitions.

## Details

The following description applies when the optional arguments are omitted, the usual case. First, the defining signatures for all methods are computed by calls to `findMethodSignatures`. From these all the known non-virtual subclasses are found for each class that appears in the signature of some method. These subclasses are split into groups according to which class they inherit from, and only one subclass from each group is retained (for each argument in the generic signature). So if a method was defined with class "vector" for some argument, one actual vector class is chosen arbitrarily. The case of "ANY" is dealt with specially, since all classes extend it. A dummy, nonvirtual class, ".Other", is used to correspond to all classes that have no superclasses among those being tested.

All combinations of retained subclasses for the arguments in the generic signature are then computed. Each row of the resulting matrix is a signature to be tested by a call to `selectMethod`. To collect information on ambiguous selections, `testInheritedMethods` establishes a calling handler for the special signal "ambiguousMethodSelection", by setting the corresponding option.

## Value

An object of class "methodSelectionReport". The details of this class are currently subject to change. It has slots "target", "selected", "candidates", and "note", all referring to the ambiguous cases (and so of length 0 if there were none). These slots are intended to be examined by the programmer to detect and preferably fix ambiguous method selections. The object contains in addition slots "generic", the name of the generic function, and "allSelections", giving the vector of labels for all the signatures tested.

## Examples

```
if no other attached packages have methods for + or its group
generic functions, this returns a 16 by 2 matrix of selection
patterns (in R 2.9.0)
testInheritedMethods("+")
```

## Description

The classes described here are used by the R function `trace` to create versions of functions and methods including browser calls, etc., and also to `untrace` the same objects.

## Usage

```
Objects from the following classes are generated
by calling trace() on an object from the corresponding
class without the "WithTrace" in the name.

"functionWithTrace"
"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

the following is a virtual class extended by each of the
classes above

"traceable"
```

## Objects from the Class

Objects will be created from these classes by calls to trace. (There is an [initialize](#) method for class "traceable", but you are unlikely to need it directly.)

## Slots

- .Data: The data part, which will be "function" for class "functionWithTrace", and similarly for the other classes.
- original: Object of the original class; e.g., "function" for class "functionWithTrace".

## Extends

Each of the classes extends the corresponding untraced class, from the data part; e.g., "functionWithTrace" extends "function". Each of the specific classes extends "traceable", directly, and class "VIRTUAL", by class "traceable".

## Methods

The point of the specific classes is that objects generated from them, by function [trace\(\)](#), remain callable or dispatchable, in addition to their new trace information.

## See Also

function [trace](#)

## Description

The validity of object related to its class definition is tested. If the object is valid, TRUE is returned; otherwise, either a vector of strings describing validity failures is returned, or an error is generated (according to whether test is TRUE). Optionally, all slots in the object can also be validated.

The function `setValidity` sets the validity method of a class (but more normally, this method will be supplied as the `validity` argument to `setClass`). The method should be a function of one object that returns TRUE or a description of the non-validity.

## Usage

```
validObject(object, test = FALSE, complete = FALSE)

setValidity(Class, method, where = topenv(parent.frame()))

getValidity(ClassDef)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | any object, but not much will happen unless the object's class has a formal definition.                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>test</code>     | logical; if TRUE and validity fails, the function returns a vector of strings describing the problems. If test is FALSE (the default) validity failure generates an error.                                                                                                                                                                                                                                                                                                      |
| <code>complete</code> | logical; if TRUE, validity methods will be applied recursively to any of the slots that have such methods.                                                                                                                                                                                                                                                                                                                                                                      |
| <code>Class</code>    | the name or class definition of the class whose validity method is to be set.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>ClassDef</code> | a class definition object, as from <code>getClassDef</code> .                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>method</code>   | a validity method; that is, either NULL or a function of one argument ( <code>object</code> ). Like <code>validObject</code> , the function should return TRUE if the object is valid, and one or more descriptive strings if any problems are found. Unlike <code>validObject</code> , it should never generate an error.                                                                                                                                                      |
| <code>where</code>    | the modified class definition will be stored in this environment.<br><br>Note that validity methods do not have to check validity of superclasses: the logic of <code>validObject</code> ensures these tests are done once only. As a consequence, if one validity method wants to use another, it should extract and call the method from the other definition of the other class by calling <code>getValidity()</code> : it should <i>not</i> call <code>validObject</code> . |

## Details

Validity testing takes place ‘bottom up’: Optionally, if `complete=TRUE`, the validity of the object’s slots, if any, is tested. Then, in all cases, for each of the classes that this class extends (the ‘superclasses’), the explicit validity method of that class is called, if one exists. Finally, the validity method of object’s class is called, if there is one.

Testing generally stops at the first stage of finding an error, except that all the slots will be examined even if a slot has failed its validity test.

The standard validity test (with `complete=FALSE`) is applied when an object is created via `new` with any optional arguments (without the extra arguments the result is just the class prototype object).

An attempt is made to fix up the definition of a validity method if its argument is not `object`.

**Value**

*validObject* returns TRUE if the object is valid. Otherwise a vector of strings describing problems found, except that if *test* is FALSE, validity failure generates an error, with the corresponding strings in the error message.

**See Also**

[setClass](#); class [classRepresentation](#).

**Examples**

```
setClass("track",
 representation(x="numeric", y = "numeric"))
t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))
A valid "track" object has the same number of x, y values
validTrackObject <- function(object) {
 if(length(object@x) == length(object@y)) TRUE
 else paste("Unequal x,y lengths: ", length(object@x), ", ",
 length(object@y), sep="")
}
assign the function as the validity method for the class
setValidity("track", validTrackObject)
t1 should be a valid "track" object
validObject(t1)
Now we do something bad
t2 <- t1
t2@x <- 1:20
This should generate an error
Not run: try(validObject(t2))

setClass("trackCurve",
 representation("track", smooth = "numeric"))

all superclass validity methods are used when validObject
is called from initialize() with arguments, so this fails
Not run: trynew("trackCurve", t2)

setClass("twoTrack", representation(tr1 = "track", tr2 ="track"))

validity tests are not applied recursively by default,
so this object is created (invalidly)
tT <- new("twoTrack", tr2 = t2)

A stricter test detects the problem
Not run: try(validObject(tT, complete = TRUE))
```

# Chapter 8

## The parallel package

---

parallel-package

*Support for Parallel Computation*

---

### Description

Support for parallel computation, including random-number generation.

### Details

This package is under development: a first version was released with R 2.14.0.

There is support for multiple RNG streams with the ‘‘LEcuyer-CMRG’’ [RNG](#): see [nextRNGStream](#).

It contains functionality derived from and pretty much equivalent to that contained in packages [multicore](#) (with some low-level functions renamed and not exported) and [snow](#) (for socket clusters only, but MPI and NWS clusters generated by [snow](#) are also supported). This package also provides [makeForkCluster](#).

For a complete list of exported functions, use `library(help = "parallel")`.

### Author(s)

Brian Ripley, Luke Tierney and Simon Urbanek

Maintainer: R Core Team <[R-core@r-project.org](mailto:R-core@r-project.org)>

### See Also

Parallel computation involves launching worker processes: functions [psnice](#) and [pskill](#) in package [tools](#) provide means to manage such processes.

---

**clusterApply***Apply Operations using Clusters*

---

**Description**

These functions provide several ways to parallelize computations using a cluster.

**Usage**

```
clusterCall(cl = NULL, fun, ...)
clusterApply(cl = NULL, x, fun, ...)
clusterApplyLB(cl = NULL, x, fun, ...)
clusterEvalQ(cl = NULL, expr)
clusterExport(cl = NULL, varlist, envir = .GlobalEnv)
clusterMap(cl = NULL, fun, ..., MoreArgs = NULL, RECYCLE = TRUE,
 SIMPLIFY = FALSE, USE.NAMES = TRUE,
 .scheduling = c("static", "dynamic"))
clusterSplit(cl = NULL, seq)

parLapply(cl = NULL, X, fun, ...)
parSapply(cl = NULL, X, FUN, ..., simplify = TRUE,
 USE.NAMES = TRUE)
parApply(cl = NULL, X, MARGIN, FUN, ...)
parRapply(cl = NULL, x, FUN, ...)
parCapply(cl = NULL, x, FUN, ...)

parLapplyLB(cl = NULL, X, fun, ...)
parSapplyLB(cl = NULL, X, FUN, ..., simplify = TRUE,
 USE.NAMES = TRUE)
```

**Arguments**

|                       |                                                                                                                                           |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cl</code>       | a cluster object, created by this package or by package <b>snow</b> . If <code>NULL</code> , use the registered default cluster.          |
| <code>fun, FUN</code> | function or character string naming a function.                                                                                           |
| <code>expr</code>     | expression to evaluate.                                                                                                                   |
| <code>seq</code>      | vector to split.                                                                                                                          |
| <code>varlist</code>  | character vector of names of objects to export.                                                                                           |
| <code>envir</code>    | environment from which to export variables                                                                                                |
| <code>x</code>        | a vector for <code>clusterApply</code> and <code>clusterApplyLB</code> , a matrix for <code>parRapply</code> and <code>parCapply</code> . |
| <code>...</code>      | additional arguments to pass to <code>fun</code> or <code>FUN</code> : beware of partial matching to earlier arguments.                   |
| <code>MoreArgs</code> | additional arguments for <code>fun</code> .                                                                                               |
| <code>RECYCLE</code>  | logical; if true shorter arguments are recycled.                                                                                          |
| <code>X</code>        | A vector (atomic or list) for <code>parLapply</code> and <code>parSapply</code> , an array for <code>parApply</code> .                    |
| <code>MARGIN</code>   | vector specifying the dimensions to use.                                                                                                  |

```
simplify, USE.NAMES
logical; see sapply.
SIMPLIFY logical; see mapply.
.scheduling should tasks be statically allocated to nodes or dynamic load-balancing used?
```

## Details

clusterCall calls a function `fun` with identical arguments . . . on each node.

clusterEvalQ evaluates a literal expression on each cluster node. It is a parallel version of [evalq](#), and is a convenience function invoking clusterCall.

clusterApply calls `fun` on the first node with arguments `seq[[1]]` and . . ., on the second node with `seq[[2]]` and . . ., and so on, recycling nodes as needed.

clusterApplyLB is a load balancing version of clusterApply. If the length `p` of `seq` is not greater than the number of nodes `n`, then a job is sent to `p` nodes. Otherwise the first `n` jobs are placed in order on the `n` nodes. When the first job completes, the next job is placed on the node that has become free; this continues until all jobs are complete. Using clusterApplyLB can result in better cluster utilization than using clusterApply, but increased communication can reduce performance. Furthermore, the node that executes a particular job is non-deterministic.

clusterMap is a multi-argument version of clusterApply, analogous to [mapply](#) and [Map](#). If `RECYCLE` is true shorter arguments are recycled (and either none or all must be of length zero); otherwise, the result length is the length of the shortest argument. Nodes are recycled if the length of the result is greater than the number of nodes. (`mapply` always uses `RECYCLE = TRUE`, and has argument `SIMPLIFY = TRUE`. `Map` always uses `RECYCLE = TRUE`.)

clusterExport assigns the values on the master R process of the variables named in `varlist` to variables of the same names in the global environment (aka ‘workspace’) of each node. The environment on the master from which variables are exported defaults to the global environment.

clusterSplit splits `seq` into a consecutive piece for each cluster and returns the result as a list with length equal to the number of nodes. Currently the pieces are chosen to be close to equal in length: the computation is done on the master.

`parLapply`, `parSapply`, and `parApply` are parallel versions of `lapply`, `sapply` and `apply`. `parLapplyLB`, `parSapplyLB` are load-balancing versions, intended for use when applying `FUN` to different elements of `X` takes quite variable amounts of time, and either the function is deterministic or reproducible results are not required.

`parRapply` and `parCapply` are parallel row and column apply functions for a matrix `x`; they may be slightly more efficient than `parApply` but do less post-processing of the result.

## Value

For `clusterCall`, `clusterEvalQ` and `clusterSplit`, a list with one element per node.

For `clusterApply` and `clusterApplyLB`, a list the same length as `seq`.

`clusterMap` follows [mapply](#).

`clusterExport` returns nothing.

`parLapply` returns a list the length of `X`.

`parSapply` and `parApply` follow [sapply](#) and [apply](#) respectively.

`parRapply` and `parCapply` always return a vector. If `FUN` always returns a scalar result this will be of length the number of rows or columns: otherwise it will be the concatenation of the returned values.

An error is signalled on the master if any of the workers produces an error.

**Note**

These functions are almost identical to those in package **snow**.

Two exceptions: `parLapply` has argument `X` not `x` for consistency with `lapply`, and `parSapply` has been updated to match `sapply`.

**Author(s)**

Luke Tierney and R Core.

Derived from the **snow** package.

**Examples**

```
Use option cl.cores to choose an appropriate cluster size.
cl <- makeCluster(getOption("cl.cores", 2))

clusterApply(cl, 1:2, get("+"), 3)
xx <- 1
clusterExport(cl, "xx")
clusterCall(cl, function(y) xx + y, 2)

Use clusterMap like an mapply example
clusterMap(cl, function(x, y) seq_len(x) + y,
 c(a = 1, b = 2, c = 3), c(A = 10, B = 0, C = -10))

parSapply(cl, 1:20, get("+"), 3)

A bootstrapping example, which can be done in many ways:
clusterEvalQ(cl, {
 ## set up each worker. Could also use clusterExport()
 library(boot)
 cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mlem, mlev)
 cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
 NULL
})
res <- clusterEvalQ(cl, boot(cd4, corr, R = 100,
 sim = "parametric", ran.gen = cd4.rg, mle = cd4.mle))
library(boot)
cd4.boot <- do.call(c, res)
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
 conf = 0.9, h = atanh, hinv = tanh)
stopCluster(cl)

or
library(boot)
run1 <- function(...) {
 library(boot)
 cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mlem, mlev)
 cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
 boot(cd4, corr, R = 500, sim = "parametric",
 ran.gen = cd4.rg, mle = cd4.mle)
}
cl <- makeCluster(mc <- getOption("cl.cores", 2))
to make this reproducible
clusterSetRNGStream(cl, 123)
```

```
cd4.boot <- do.call(c, parLapply(cl, seq_len(mc), run1))
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
 conf = 0.9, h = atanh, hinv = tanh)
stopCluster(cl)
```

---

**detectCores***Detect the Number of CPU Cores*

---

**Description**

Attempt to detect the number of CPU cores on the current host.

**Usage**

```
detectCores(all.tests = FALSE, logical = FALSE)
```

**Arguments**

- |           |                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------|
| all.tests | Logical: if true apply all known tests.                                                           |
| logical   | Logical: if possible, use the number of physical CPUs/cores (if FALSE) or logical CPUs (if TRUE). |

**Details**

This attempts to detect the number of CPU cores in the current machine.

It has methods to do so for Linux, OS X, FreeBSD, Solaris, Irix and Windows. `detectCores(TRUE)` could be tried on other Unix-alike systems.

**Value**

An integer, NA if the answer is unknown.

Exactly what this represents is OS-dependent: where possible by default it represents physical cores and not logical (e.g. hyperthreaded) CPUs.

On Windows the default is the number of logical CPUs.

Currently `logical` makes a difference on Sparc Solaris: there `logical = FALSE` returns the number of physical cores and `logical = TRUE` returns the number of available hardware threads. (Some Sparc CPUs which do have multiple cores per CPU, others have multiple threads per core and some have both.) For example, the UltraSparc T2 CPU in the CRAN check server is a single physical CPU with 8 cores, and each core supports 8 hardware threads. So `detectCores(logical = FALSE)` returns 8, and `detectCores(logical = TRUE)` returns 64.

Where virtual machines are in use, one would hope that the result represents the number of CPUs available (or potentially available) to that particular VM.

**Author(s)**

Simon Urbanek and Brian Ripley

**Examples**

```
detectCores()
detectCores(logical = TRUE)
```

**makeCluster***Create a Parallel Socket Cluster***Description**

Creates a set of copies of R running in parallel and communicating over sockets.

**Usage**

```
makeCluster(spec, type, ...)
makePSOCKcluster(names, ...)
makeForkCluster(nnodes = getOption("mc.cores", 2L), ...)

stopCluster(cl = NULL)

setDefaultCluster(cl = NULL)
```

**Arguments**

|                     |                                                                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>spec</code>   | A specification appropriate to the type of cluster.                                                                                                                |
| <code>names</code>  | Either a character vector of host names on which to run the worker copies of R, or a positive integer (in which case that number of copies is run on ‘localhost’). |
| <code>nnodes</code> | The number of nodes to be forked.                                                                                                                                  |
| <code>type</code>   | One of the supported types: see ‘Details’.                                                                                                                         |
| <code>...</code>    | Options to be passed to the function spawning the workers. See ‘Details’.                                                                                          |
| <code>cl</code>     | an object of class “cluster”.                                                                                                                                      |

**Details**

`makeCluster` creates a cluster of one of the supported types. The default type, "PSOCK", calls `makePSOCKcluster`. Type "FORK" calls `makeForkCluster`. Other types are passed to package **snow**.

`makePSOCKcluster` is very similar to `makeSOCKcluster` in package **snow**. It runs `Rscript` on the specified host(s) to set up a worker process which listens on a socket for expressions to evaluate, and returns the results (as serialized objects).

`makeForkCluster` is merely a stub on Windows. On Unix-alike platforms it creates the worker process by forking.

The workers are most often running on the same host as the master, when no options need be set.

Several options are supported (mainly for `makePSOCKcluster`):

- `master` The host name of the master, as known to the workers. This may not be the same as it is known to the master, and on private subnets it may be necessary to specify this as a numeric IP address. For example, OS X is likely to detect a machine as ‘`somename.local`’, a name known only to itself.
- `port` The port number for the socket connection, default taken from the environment variable `R_PARALLEL_PORT`, then a randomly chosen port in the range 11000:11999.
- `timeout` The timeout in seconds for that port. Default 30 days (and the POSIX standard only requires values up to 31 days to be supported).

**outfile** Where to direct the `stdout` and `stderr` connection output from the workers. `""` indicates no redirection (which may only be useful for workers on the local machines). Defaults to `'/dev/null'` ('`nul:`' on Windows). The other possibility is a file path on the worker's host. Files will be opened in append mode, as all workers log to the same file.

**homogeneous** Logical. Are all the hosts running identical setups, so `Rscript` can be launched using its full path on the master? Otherwise it has to be in the default path on the other hosts.

**rscript** The path to `Rscript` on the workers. Defaults to the full path on the master.

**renice** A numerical ‘niceness’ to set for the worker processes, e.g. 15 for a low priority. OS-dependent: see `psnice` for details.

**rshcmd** The command to be run on the master to launch a process on another host. Defaults to `ssh`.

**user** The user name to be used when communicating with another host.

**manual** Logical. If true the workers will need to be run manually.

**methods** Logical. If true (default) the workers will load the **methods** package: not loading it saves ca 30% of the startup time of the cluster.

**useXDR** Logical. If true (default) serialization will use XDR: where large amounts of data are to be transferred and all the nodes are little-endian, communication may be substantially fast if this is set to false.

Function `makeForkCluster` creates a socket cluster by forking (and hence is not available on Windows). It supports options `port`, `timeout` and `outfile`, and always uses `useXDR = FALSE`.

It is good practice to shut down the workers by calling `stopCluster`: however the workers will terminate themselves once the socket on which they are listening for commands becomes unavailable, which it should if the master R session is completed (or its process dies).

Function `setDefaultCluster` registers a cluster as the default one for the current session. Using `setDefaultCluster(NULL)` removes the registered cluster, as does stopping that cluster.

## Value

An object of class `c("SOCKcluster", "cluster")`.

## Author(s)

Luke Tierney and R Core.

Derived from the **snow** package.

## Description

`mcaffinity` retrieves or sets the CPU affinity mask of the current process, i.e., the set of CPUs the process is allowed to be run on. (CPU here means logical CPU which can be CPU, core or hyperthread unit.)

## Usage

```
mcaffinity(affinity = NULL)
```

### Arguments

|                       |                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>affinity</code> | specification of the CPUs to lock this process to (numeric vector) or <code>NULL</code> if no change is requested |
|-----------------------|-------------------------------------------------------------------------------------------------------------------|

### Details

`mcaffinity` can be used to obtain (`affinity = NULL`) or set the CPU affinity mask of the current process. The affinity mask is a list of integer CPU identifiers (starting from 1) that this process is allowed to run on. Not all systems provide user access to the process CPU affinity, in cases where no support is present at all `mcaffinity()` will return `NULL`. Some systems may take into account only the number of CPUs present in the mask.

Typically, it is legal to specify larger set than the number of logical CPUs (but at most as many as the OS can handle) and the system will return back the actually present set.

### Value

`NULL` if CPU affinity is not supported by the system or an integer vector with the set of CPUs in the active affinity mask for this process (this may be different than `affinity`).

### Description

These are low-level support functions for the forking approach.

They are not available on Windows, and not exported from the namespace.

### Usage

```
children(select)
readChild(child)
readChildren(timeout = 0)
selectChildren(children = NULL, timeout = 0)
sendChildStdin(child, what)
sendMaster(what)

mckill(process, signal = 2L)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>select</code>   | if omitted, all active children are returned, otherwise <code>select</code> should be a list of processes and only those from the list that are active will be returned.                                                                                                                                                                                                                                                             |
| <code>child</code>    | child process (object of the class "childProcess") or a process ID (pid). See also 'Details'.                                                                                                                                                                                                                                                                                                                                        |
| <code>timeout</code>  | timeout (in seconds, fractions supported) to wait for a response before giving up.                                                                                                                                                                                                                                                                                                                                                   |
| <code>children</code> | list of child processes or a single child process object or a vector of process IDs or NULL. If NULL behaves as if all currently known children were supplied.                                                                                                                                                                                                                                                                       |
| <code>what</code>     | <p>For <code>sendChildStdin</code>:</p> <p>Character or raw vector. In the former case elements are collapsed using the newline character. (But no trailing newline is added at the end!)</p> <p>For <code>sendMaster</code>:</p> <p>Data to send to the master process. If <code>what</code> is not a raw vector, it will be serialized into a raw vector. Do NOT send an empty raw vector – that is reserved for internal use.</p> |
| <code>process</code>  | process (object of the class <code>process</code> ) or a process ID (pid)                                                                                                                                                                                                                                                                                                                                                            |
| <code>signal</code>   | integer: signal to send. Values of 2 (SIGINT), 9 (SIGKILL) and 15 (SIGTERM) are pretty much portable, but for maximal portability use <code>tools::SIGTERM</code> and so on.                                                                                                                                                                                                                                                         |

### Details

`children` returns currently active children.

`readChild` reads data from a given child process.

`selectChildren` checks children for available data.

`readChildren` checks all children for available data and reads from the first child that has available data.

`sendChildStdin` sends a string (or data) to one or more child's standard input. Note that if the master session was interactive, it will also be echoed on the standard output of the master process (unless disabled). The function is vector-compatible, so you can specify `child` as a list or a vector of process IDs.

`sendMaster` sends data from the child to the master process.

`mckill` sends a signal to a child process: it is equivalent to `pskill` in package `tools`.

### Value

`children` returns a (possibly empty) list of objects of class "process", the process ID.

`readChild` and `readChildren` return a raw vector with a "pid" attribute if data were available, an integer vector of length one with the process ID if a child terminated or NULL if the child no longer exists (no children at all for `readChildren`).

`selectChildren` returns TRUE if the timeout was reached, FALSE if an error occurred (e.g. if the master process was interrupted) or an integer vector of process IDs with children that have data available, or NULL if there are no children.

`sendChildStdin` returns a vector of TRUE values (one for each member of `child`) or throws an error.

`sendMaster` returns TRUE or throws an error.

`mckill` returns TRUE.

mccollect(p)[[1]]

End(Not run)
```

---

**mcfork**

*Fork a Copy of the Current R Process*

---

## Description

These are low-level functions, not available on Windows, and not exported from the namespace.

**mcfork** creates a new child process as a copy of the current R process.

**mexit** closes the current child process, informing the master process as necessary.

## Usage

```
mcfork()

mexit(exit.code = 0L, send = NULL)
```

## Arguments

|                  |                                                                                              |
|------------------|----------------------------------------------------------------------------------------------|
| <b>exit.code</b> | process exit code. By convention 0L signifies a clean exit, 1L an error.                     |
| <b>send</b>      | if not NULL send this data before exiting (equivalent to using <a href="#">sendMaster</a> ). |

## Details

The **mcfork** function provides an interface to the fork system call. In addition it sets up a pipe between the master and child process that can be used to send data from the child process to the master (see [sendMaster](#)) and child's 'stdin' is re-mapped to another pipe held by the master process (see [sendChildStdin](#)).

If you are not familiar with the fork system call, do not use this function directly as it leads to very complex inter-process interactions amongst the R processes involved.

In a nutshell fork spawns a copy (child) of the current process, that can work in parallel to the master (parent) process. At the point of forking both processes share exactly the same state including the workspace, global options, loaded packages etc. Forking is relatively cheap in modern operating systems and no real copy of the used memory is created, instead both processes share the same memory and only modified parts are copied. This makes mcfork an ideal tool for parallel processing since there is no need to setup the parallel working environment, data and code is shared automatically from the start.

mcexit is to be run in the child process. It sends send to the master (unless NULL) and then shuts down the child process. The child can also be shut down by sending it the signal SIGUSR1, as is done by the unexported function `parallel:::rmChild`.

### Value

`mcfork` returns an object of the class "childProcess" to the master and of class "masterProcess" to the child: both the classes inherit from class "process". These are lists with components `pid` (the process id of the *other* process) and a vector `fd` of the two file descriptor numbers for ends in the current process of the inter-process pipes.

`mcexit` never returns.

### GUI/embedded environments

It is *strongly discouraged* to use `mcfork` and the higher-level functions which rely on it (e.g., `mcremote`, `mclapply` and `pvec`) in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices. Some precautions have been taken to make this usable in R.app on OS X, but users of third-party front-ends should consult their documentation.

This can also apply to other connections, e.g. to an X server, created before forking.

Note that **tcltk** counts as a GUI for these purposes since `Tcl` runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

### Warning

This is a very low-level API for expert use only.

### Examples

```
This will work when run as an example, but not when pasted in.
p <- mcfork()
if (inherits(p, "masterProcess")) {
 cat("Im a child! ", Sys.getpid(), "\n")
 mcexit("I was a child")
}
cat("Im the master\n")
unserialize(readChildren(1.5))
```

---

**mclapply***Parallel Versions of lapply and mapply using Forking*

---

### Description

`mclapply` is a parallelized version of `lapply`, it returns a list of the same length as `X`, each element of which is the result of applying `FUN` to the corresponding element of `X`.

It relies on forking and hence is not available on Windows unless `mc.cores = 1`.

`mcmapply` is a parallelized version of `mapply`, and `mcMap` corresponds to `Map`.

### Usage

```
mclapply(X, FUN, ...,
 mc.preschedule = TRUE, mc.set.seed = TRUE,
 mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L),
 mc.cleanup = TRUE, mc.allow.recursive = TRUE)

mcmapply(FUN, ...,
 MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE,
 mc.preschedule = TRUE, mc.set.seed = TRUE,
 mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L),
 mc.cleanup = TRUE)

mcMap(f, ...)
```

### Arguments

|                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <code>mc.silent</code>                                                 | if set to <code>TRUE</code> then all output on ‘ <code>stdout</code> ’ will be suppressed for all parallel processes forked (‘ <code>stderr</code> ’ is not affected).                                                                                                                                                                                                                                                                                                                                                                |
| <code>mc.cores</code>                                                  | The number of cores to use, i.e. at most how many child processes will be run simultaneously. The option is initialized from environment variable <code>MC_CORES</code> if set. Must be at least one, and parallelization requires at least two cores.                                                                                                                                                                                                                                                                                |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mc.cleanup         | if set to TRUE then all children that have been forked by this function will be killed (by sending SIGTERM) before this function returns. Under normal circumstances mcapply waits for the children to deliver results, so this option usually has only effect when mcapply is interrupted. If set to FALSE then child processes are collected, but not forcefully terminated. As a special case this argument can be set to the number of the signal that should be used to kill the children instead of SIGTERM. |
| mc.allow.recursive | Unless true, calling mcapply in a child process will use the child and not fork again.                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

mcapply is a parallelized version of [lapply](#), provided `mc.cores > 1`: for `mc.cores == 1` it simply calls lapply.

By default (`mc.preschedule = TRUE`) the input X is split into as many parts as there are cores (currently the values are spread across the cores sequentially, i.e. first value to core 1, second to core 2, ... (core + 1)-th value to core 1 etc.) and then one process is forked to each core and the results are collected.

Without prescheduling, a separate job is forked for each value of X. To ensure that no more than `mc.cores` jobs are running at once, once that number has been forked the master process waits for a child to complete before the next fork.

Due to the parallel nature of the execution random numbers are not sequential (in the random number sequence) as they would be when using lapply. They are sequential for each forked process, but not all jobs as a whole. See [mcparallel](#) or the package's vignette for ways to make the results reproducible with `mc.preschedule = TRUE`.

Note: the number of file descriptors (and processes) is usually limited by the operating system, so you may have trouble using more than 100 cores or so (see `ulimit -n` or similar in your OS documentation) unless you raise the limit of permissible open file descriptors (fork will fail with error "unable to create a pipe").

## Value

For mcapply, a list of the same length as X and named by X.

For mcmapply, a list, vector or array: see [mapply](#).

For mcMap, a list.

Each forked process runs its job inside `try(..., silent = TRUE)` so if errors occur they will be stored as class "try-error" objects in the return value and a warning will be given. Note that the job will typically involve more than one value of X and hence a "try-error" object will be returned for all the values involved in the failure, even if not all of them failed.

## Warning

It is *strongly discouraged* to use these functions in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices.

Some precautions have been taken to make this usable in R.app on OS X, but users of third-party front-ends should consult their documentation.

Note that **tcltk** counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

**Author(s)**

Simon Urbanek and R Core.

Derived from the **multicore** package.

**See Also**

[mcparrallel](#), [pvec](#), [parLapply](#), [clusterMap](#).

[simplify2array](#) for results like [sapply](#).

**Examples**

```
simplify2array(mclapply(rep(4, 5), rnorm))
use the same random numbers for all values
set.seed(1)
simplify2array(mclapply(rep(4, 5), rnorm, mc.preschedule = FALSE,
 mc.set.seed = FALSE))

Contrast this with the examples for clusterCall
library(boot)
cd4.rg <- function(data, mle) MASS::mvtnorm(nrow(data), mlem, mlev)
cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
mc <- getOption("mc.cores", 2)
run1 <- function(...) boot(cd4, corr, R = 500, sim = "parametric",
 ran.gen = cd4.rg, mle = cd4.mle)
To make this reproducible:
set.seed(123, "L'Ecuyer")
res <- mclapply(seq_len(mc), run1)
cd4.boot <- do.call(c, res)
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
 conf = 0.9, h = atanh, hinv = tanh)
```

**Description**

These functions are based on forking and so are not available on Windows.

**mcparrallel** starts a parallel R process which evaluates the given expression.

**mccollect** collects results from one or more parallel processes.

**Usage**

```
mcparrallel(expr, name, mc.set.seed = TRUE, silent = FALSE,
 mc.affinity = NULL, mc.interactive = FALSE)
```

```
mccollect(jobs, wait = TRUE, timeout = 0, intermediate = FALSE)
```

## Arguments

|                             |                                                                                                                                                                                              |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expr</code>           | expression to evaluate (do <i>not</i> use any on-screen devices or GUI elements in this code).                                                                                               |
| <code>name</code>           | an optional name (character vector of length one) that can be associated with the job.                                                                                                       |
| <code>mc.set.seed</code>    | logical: see section ‘Random numbers’.                                                                                                                                                       |
| <code>silent</code>         | if set to TRUE then all output on stdout will be suppressed (stderr is not affected).                                                                                                        |
| <code>mc.affinity</code>    | either a numeric vector specifying CPUs to restrict the child process to (1-based) or NULL to not modify the CPU affinity                                                                    |
| <code>mc.interactive</code> | logical, if TRUE or FALSE then the child process will be set as interactive or non-interactive respectively. If NA then the child process will inherit the interactive flag from the parent. |
| <code>jobs</code>           | list of jobs (or a single job) to collect results for. Alternatively jobs can also be an integer vector of process IDs. If omitted collect will wait for all currently existing children.    |
| <code>wait</code>           | if set to FALSE it checks for any results that are available within <code>timeout</code> seconds from now, otherwise it waits for all specified jobs to finish.                              |
| <code>timeout</code>        | <code>timeout</code> (in seconds) to check for job results – applies only if <code>wait</code> is FALSE.                                                                                     |
| <code>intermediate</code>   | FALSE or a function which will be called while collect waits for results. The function will be called with one parameter which is the list of results received so far.                       |

## Details

`mcparallel` evaluates the `expr` expression in parallel to the current R process. Everything is shared read-only (or in fact copy-on-write) between the parallel process and the current process, i.e. no side-effects of the expression affect the main process. The result of the parallel execution can be collected using `mccollect` function.

`mccollect` function collects any available results from parallel jobs (or in fact any child process). If `wait` is TRUE then `collect` waits for all specified jobs to finish before returning a list containing the last reported result for each job. If `wait` is FALSE then `mccollect` merely checks for any results available at the moment and will not wait for jobs to finish. If `jobs` is specified, jobs not listed there will not be affected or acted upon.

Note: If `expr` uses low-level multicore functions such as `sendMaster` a single job can deliver results multiple times and it is the responsibility of the user to interpret them correctly. `mccollect` will return NULL for a terminating job that has sent its results already after which the job is no longer available.

The `mc.affinity` parameter can be used to try to restrict the child process to specific CPUs. The availability and the extent of this feature is system-dependent (e.g., some systems will only consider the CPU count, others will ignore it completely).

## Value

`mcparallel` returns an object of the class “parallelJob” which inherits from “childProcess” (see the ‘Value’ section of the help for `mcfork`). If argument `name` was supplied this will have an additional component `name`.

`mccollect` returns any results that are available in a list. The results will have the same order as the specified jobs. If there are multiple jobs and a job has a name it will be used to name the result, otherwise its process ID will be used. If none of the specified children are still running, it returns NULL.

## Random numbers

If `mc.set.seed = FALSE`, the child process has the same initial random number generator (RNG) state as the current R session. If the RNG has been used (or `.Random.seed` was restored from a saved workspace), the child will start drawing random numbers at the same point as the current session. If the RNG has not yet been used, the child will set a seed based on the time and process ID when it first uses the RNG: this is pretty much guaranteed to give a different random-number stream from the current session and any other child process.

The behaviour with `mc.set.seed = TRUE` is different only if `RNGkind("L'Ecuyer-CMRG")` has been selected. Then each time a child is forked it is given the next stream (see `nextRNGStream`). So if you select that generator, set a seed and call `mc.reset.stream` just before the first use of `mparallel` the results of simulations will be reproducible provided the same tasks are given to the first, second, ... forked process.

## Note

Package **multicore** also exported functions `collect` and `parallel`. These names are easily masked (for example package **lattice** also has a function `parallel`) and they are not supplied in this package.

## Author(s)

Simon Urbanek and R Core.

Derived from the **multicore** package (but with different handling of the RNG stream).

## See Also

`pvec`, `mclapply`

## Examples

```

p <- mparallel(1:10)
q <- mparallel(1:20)
wait for both jobs to finish and collect all results
res <- mcollect(list(p, q))

p <- mparallel(1:10)
mcollect(p, wait = FALSE, 10) # will retrieve the result (since its fast)
mcollect(p, wait = FALSE) # will signal the job as terminating
mcollect(p, wait = FALSE) # there is no longer such a job

a naive parallel lapply can be created using mparallel alone:
jobs <- lapply(1:10, function(x) mparallel(rnorm(x), name = x))
mcollect(jobs)

```

## Description

pvec parallelizes the execution of a function on vector elements by splitting the vector and submitting each part to one core. The function must be a vectorized map, i.e. it takes a vector input and creates a vector output of exactly the same length as the input which doesn't depend on the partition of the vector.

It relies on forking and hence is not available on Windows unless `mc.cores = 1`.

## Usage

```
pvec(v, FUN, ..., mc.set.seed = TRUE, mc.silent = FALSE,
 mc.cores = getOption("mc.cores", 2L), mc.cleanup = TRUE)
```

## Arguments

|                          |                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>v</code>           | vector to operate on                                                                                                                                                                                                                           |
| <code>FUN</code>         | function to call on each part of the vector                                                                                                                                                                                                    |
| <code>...</code>         | any further arguments passed to <code>FUN</code> after the vector                                                                                                                                                                              |
| <code>mc.set.seed</code> | See <a href="#">mcparallel</a> .                                                                                                                                                                                                               |
| <code>mc.silent</code>   | if set to <code>TRUE</code> then all output on ‘ <code>stdout</code> ’ will be suppressed for all parallel processes forked (‘ <code>stderr</code> ’ is not affected).                                                                         |
| <code>mc.cores</code>    | The number of cores to use, i.e. at most how many child processes will be run simultaneously. Must be at least one, and at least two for parallel operation. The option is initialized from environment variable <code>MC_CORES</code> if set. |
| <code>mc.cleanup</code>  | See the description of this argument in <a href="#">mclapply</a> .                                                                                                                                                                             |

## Details

`pvec` parallelizes `FUN(x, ...)` where `FUN` is a function that returns a vector of the same length as `x`. `FUN` must also be pure (i.e., without side-effects) since side-effects are not collected from the parallel processes. The vector is split into nearly identically sized subvectors on which `FUN` is run. Although it is in principle possible to use functions that are not necessarily maps, the interpretation would be case-specific as the splitting is in theory arbitrary (a warning is given in such cases).

The major difference between `pvec` and [mclapply](#) is that `mclapply` will run `FUN` on each element separately whereas `pvec` assumes that `c(FUN(x[1]), FUN(x[2]))` is equivalent to `FUN(x[1:2])` and thus will split into as many calls to `FUN` as there are cores (or elements, if fewer), each handling a subset vector. This makes it more efficient than `mclapply` but requires the above assumption on `FUN`.

If `mc.cores == 1` this evaluates `FUN(v, ...)` in the current process.

## Value

The result of the computation – in a successful case it should be of the same length as `v`. If an error occurred or the function was not a map the result may be shorter or longer, and a warning is given.

## Note

Due to the nature of the parallelization, error handling does not follow the usual rules since errors will be returned as strings and results from killed child processes will show up simply as nonexistent data. Therefore it is the responsibility of the user to check the length of the result to make

sure it is of the correct size. `pvec` raises a warning if that is the case since it does not know whether such an outcome is intentional or not.

See [mcfork](#) for the inadvisability of using this with GUI front-ends.

### Author(s)

Simon Urbanek and R Core.

Derived from the [multicore](#) package.

### See Also

[mparallel](#), [mclapply](#), [parLapply](#), [clusterMap](#).

### Examples

```
x <- pvec(1:1000, sqrt)
stopifnot(all(x == sqrt(1:1000)))

One use is to convert date strings to unix time in large datasets
as that is a relatively slow operation.
So lets get some random dates first
(A small test only with 2 cores: set options("mc.cores")
and increase N for a larger-scale test.)
N <- 1e4
dates <- sprintf("%04d-%02d-%02d", as.integer(2000+rnorm(N)),
 as.integer(runif(N, 1, 12)), as.integer(runif(N, 1, 28)))

system.time(a <- as.POSIXct(dates))
This ought to be faster, but system overhead can be high
- and is on OS X Lion
system.time(b <- pvec(dates, as.POSIXct))
stopifnot(all(a == b))

using mclapply for this would much slower because each value
will require a separate call to as.POSIXct()
as lapply(dates, as.POSIXct) does
system.time(c <- unlist(mclapply(dates, as.POSIXct))
```

### Description

This is an R re-implementation of Pierre L'Ecuyer's 'RngStreams' multiple streams of pseudo-random numbers.

### Usage

```
nextRNGStream(seed)
nextRNGSubStream(seed)

clusterSetRNGStream(cl = NULL, iseed)
mc.reset.stream()
```

## Arguments

|       |                                                                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| seed  | An integer vector of length 7 as given by <code>.Random.seed</code> when the "L'Ecuyer-CMRG" RNG is in use. See <a href="#">RNG</a> for the valid values. |
| c1    | A cluster from this package or package <a href="#">snow</a> , or (if NULL) the registered cluster.                                                        |
| iseed | An integer to be supplied to <a href="#">set.seed</a> , or NULL not to set reproducible seeds.                                                            |

## Details

The 'RngStream' interface works with (potentially) multiple streams of pseudo-random numbers: this is particularly suitable for working with parallel computations since each task can be assigned a separate RNG stream.

This uses as its underlying generator `RNGkind("L'Ecuyer-CMRG")`, of L'Ecuyer (1999), which has a seed vector of 6 (signed) integers and a period of around  $2^{191}$ . Each 'stream' is a subsequence of the period of length  $2^{127}$  which is in turn divided into 'substreams' of length  $2^{76}$ .

The idea of L'Ecuyer *et al* (2002) is to use a separate stream for each of the parallel computations (which ensures that the random numbers generated never get into sync) and the parallel computations can themselves use substreams if required. The original interface stores the original seed of the first stream, the original seed of the current stream and the current seed: this could be implemented in R, but it is as easy to work by saving the relevant values of `.Random.seed`: see the examples.

`clusterSetRNGStream` selects the "L'Ecuyer-CMRG" RNG and then distributes streams to the members of a cluster, optionally setting the seed of the streams by `set.seed(iseed)` (otherwise they are set from the current seed of the master process: after selecting the L'Ecuyer generator).

Calling `mc.reset.stream()` after setting the L'Ecuyer random number generator and seed makes runs from `mcreparallel(mc.set.seed = TRUE)` reproducible. This is done internally in `mclapply` and `pvec`. (Note that it does not set the seed in the master process, so does not affect the fallback-to-serial versions of these functions.)

## Value

For `nextRNGStream` and `nextRNGSubStream`, a value which can be assigned to `.Random.seed`.

## Note

Interfaces to L'Ecuyer's C code are available in CRAN packages [rlecuyer](#) and [rstream](#).

set.seed(123)
(s <- .Random.seed)
do some work involving random numbers.
nextRNGStream(s)
nextRNGSubStream(s)
```

**splitIndices***Divide Tasks for Distribution in a Cluster***Description**

This divides up `1:nx` into `ncl` lists of approximately equal size, as a way to allocate tasks to nodes in a cluster.

It is mainly for internal use, but some package authors have found it useful.

**Usage**

```
splitIndices(nx, ncl)
```

**Arguments**

|                  |                          |
|------------------|--------------------------|
| <code>nx</code>  | Number of tasks.         |
| <code>ncl</code> | Number of cluster nodes. |

**Value**

A list of length `ncl`, each element being an integer vector.

**Examples**

```
splitIndices(20, 3)
```

# Chapter 9

## The splines package

---

splines-package

*Regression Spline Functions and Classes*

---

### Description

Regression spline functions and classes.

### Details

This package provides functions for working with regression splines using the B-spline basis, [bs](#), and the natural cubic spline basis, [ns](#).

For a complete list of functions, use `library(help = "splines")`.

### Author(s)

asVector

*Coerce an Object to a Vector*

---

### Description

This is a generic function. Methods for this function coerce objects of given classes to vectors.

### Usage

`asVector(object)`

### Arguments

object An object.

**Details**

Methods for vector coercion in new classes must be created for the `asVector` generic instead of `as.vector`. The `as.vector` function is internal and not easily extended. Currently the only class with an `asVector` method is the `xyVector` class.

**Value**

a vector

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

[xyVector](#)

**Examples**

```
require(stats)
ispl <- interpSpline(weight ~ height, women)
pred <- predict(ispl)
class(pred)
utils::str(pred)
asVector(pred)
```

**backSpline**

*Monotone Inverse Spline*

**Description**

Create a monotone inverse of a monotone natural spline.

**Usage**

`backSpline(object)`

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object that inherits from class <code>nbSpline</code> or <code>npolySpline</code> . That is, the object must represent a natural interpolation spline but it can be either in the B-spline representation or the piecewise polynomial one. The spline is checked to see if it represents a monotone function. |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Value**

An object of class `polySpline` that contains the piecewise polynomial representation of a function that has the appropriate values and derivatives at the knot positions to be an inverse of the spline represented by `object`. Technically this object is not a spline because the second derivative is not constrained to be continuous at the knot positions. However, it is often a much better approximation to the inverse than fitting an interpolation spline to the y/x pairs.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

[interpSpline](#)

**Examples**

```
require(graphics)
ispl <- interpSpline(women$height, women$weight)
bspl <- backSpline(ispl)
plot(bspl) # plots over the range of the knots
points(women$weight, women$height)
```

bs

*B-Spline Basis for Polynomial Splines*

**Description**

Generate the B-spline basis matrix for a polynomial spline.

**Usage**

```
bs(x, df = NULL, knots = NULL, degree = 3, intercept = FALSE,
 Boundary.knots = range(x))
```

**Arguments**

|                |                                                                                                                                                                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x              | the predictor variable. Missing values are allowed.                                                                                                                                                                                                                                |
| df             | degrees of freedom; one can specify df rather than knots; bs() then chooses df-degree (minus one if there is an intercept) knots at suitable quantiles of x (which will ignore missing values). The default, NULL, corresponds to <i>no</i> inner knots, i.e., degree - intercept. |
| knots          | the <i>internal</i> breakpoints that define the spline. The default is NULL, which results in a basis for ordinary polynomial regression. Typical values are the mean or median for one knot, quantiles for more knots. See also Boundary.knots.                                   |
| degree         | degree of the piecewise polynomial—default is 3 for cubic splines.                                                                                                                                                                                                                 |
| intercept      | if TRUE, an intercept is included in the basis; default is FALSE.                                                                                                                                                                                                                  |
| Boundary.knots | boundary points at which to anchor the B-spline basis (default the range of the data). If both knots and Boundary.knots are supplied, the basis parameters do not depend on x. Data can extend beyond Boundary.knots.                                                              |

**Details**

bs is based on the function [spline.des](#). It generates a basis matrix for representing the family of piecewise polynomials with the specified interior knots and degree, evaluated at the values of x. A primary use is in modeling formulas to directly specify a piecewise polynomial term in a model.

**Value**

A matrix of dimension  $c(\text{length}(x), \text{df})$ , where either df was supplied or if knots were supplied,  $\text{df} = \text{length}(\text{knots}) + \text{degree}$  plus one if there is an intercept. Attributes are returned that correspond to the arguments to bs, and explicitly give the knots, Boundary.knots etc for use by predict.bs().

**Examples**

```
require(stats); require(graphics)
bs(women$height, df = 5)
summary(fm1 <- lm(weight ~ bs(height, df = 5), data = women))

example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))
```

**interpSpline**

*Create an Interpolation Spline*

**Description**

Create an interpolation spline, either from x and y vectors, or from a formula/data.frame combination.

**Usage**

```
interpSpline(obj1, obj2, bSpline = FALSE, period = NULL,
 na.action = na.fail)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| obj1      | Either a numeric vector of x values or a formula.                                                                                                                                                                                                                                           |
| obj2      | If obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula.                                                                                                               |
| bSpline   | If TRUE the b-spline representation is returned, otherwise the piecewise polynomial representation is returned. Defaults to FALSE.                                                                                                                                                          |
| period    | An optional positive numeric value giving a period for a periodic interpolation spline.                                                                                                                                                                                                     |
| na.action | a optional function which indicates what should happen when the data contain NAs. The default action (na.omit) is to omit any incomplete observations. The alternative action na.fail causes interpSpline to print an error message and terminate if there are any incomplete observations. |

**Value**

An object that inherits from class `spline`. The object can be in the B-spline representation, in which case it will be of class `nbSpline` for natural B-spline, or in the piecewise polynomial representation, in which case it will be of class `npolySpline`.

`splineKnots`, `splineOrder`, `periodicSpline`.

**Examples**

```
require(graphics); require(stats)
ispl <- interpSpline(women$height, women$weight)
ispl2 <- interpSpline(weight ~ height, women)
ispl and ispl2 should be the same
plot(predict(ispl, seq(55, 75, length.out = 51)), type = "l")
points(women$height, women$weight)
plot(ispl) # plots over the range of the knots
points(women$height, women$weight)
splineKnots(ispl)
```

ns

*Generate a Basis Matrix for Natural Cubic Splines*

**Description**

Generate the B-spline basis matrix for a natural cubic spline.

**Usage**

```
ns(x, df = NULL, knots = NULL, intercept = FALSE,
 Boundary.knots = range(x))
```

**Arguments**

|                |                                                                                                                                                                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x              | the predictor variable. Missing values are allowed.                                                                                                                                                                                                                                       |
| df             | degrees of freedom. One can supply df rather than knots; <code>ns()</code> then chooses $df - 1 - \text{intercept}$ knots at suitably chosen quantiles of x (which will ignore missing values). The default, $df = 1$ , corresponds to no knots.                                          |
| knots          | breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on x. Typical values are the mean or median for one knot, quantiles for more knots. See also <code>Boundary.knots</code> .       |
| intercept      | if TRUE, an intercept is included in the basis; default is FALSE.                                                                                                                                                                                                                         |
| Boundary.knots | boundary points at which to impose the natural boundary conditions and anchor the B-spline basis (default the range of the data). If both knots and <code>Boundary.knots</code> are supplied, the basis parameters do not depend on x. Data can extend beyond <code>Boundary.knots</code> |

## Details

`ns` is based on the function [spline.des](#). It generates a basis matrix for representing the family of piecewise-cubic splines with the specified sequence of interior knots, and the natural boundary conditions. These enforce the constraint that the function is linear beyond the boundary knots, which can either be supplied or default to the extremes of the data.

A primary use is in modeling formula to directly specify a natural spline term in a model: see the examples.

## Value

A matrix of dimension `length(x) * df` where either `df` was supplied or if `knots` were supplied, `df = length(knots) + 1 + intercept`. Attributes are returned that correspond to the arguments to `ns`, and explicitly give the `knots`, `Boundary.knots` etc for use by `predict.ns()`.

## Examples

```
require(stats); require(graphics)
ns(women$height, df = 5)
summary(fm1 <- lm(weight ~ ns(height, df = 5), data = women))

To see what knots were selected
attr(terms(fm1), "predvars")

example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))
```

## Description

Create a periodic interpolation spline, either from `x` and `y` vectors, or from a formula/data.frame combination.

## Usage

```
periodicSpline(obj1, obj2, knots, period = 2*pi, ord = 4)
```

**Arguments**

|        |                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| obj1   | either a numeric vector of x values or a formula.                                                                                                                             |
| obj2   | if obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula. |
| knots  | optional numeric vector of knot positions.                                                                                                                                    |
| period | positive numeric value giving the period for the periodic spline. Defaults to $2 * \pi$ .                                                                                     |
| ord    | integer giving the order of the spline, at least 2. Defaults to 4. See <a href="#">splineOrder</a> for a definition of the order of a spline.                                 |

**Value**

An object that inherits from class `spline`. The object can be in the B-spline representation, in which case it will be a `pbSpline` object, or in the piecewise polynomial representation (a `ppolySpline` object).

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

[splineKnots](#), [interpSpline](#)

**Examples**

```
require(graphics); require(stats)
xx <- seq(-pi, pi, length.out = 16)[-1]
yy <- sin(xx)
frm <- data.frame(xx, yy)
pispl <- periodicSpline(xx, yy, period = 2 * pi)
pispl
pispl2 <- periodicSpline(yy ~ xx, frm, period = 2 * pi)
stopifnot(all.equal(pispl, pispl2)) # pispl and pispl2 are the same

plot(pispl) # displays over one period
points(yy ~ xx, col = "brown")
plot(predict(pispl, seq(-3*pi, 3*pi, length.out = 101)), type = "l")
```

**Description**

Create the piecewise polynomial representation of a spline object.

**Usage**

```
polySpline(object, ...)
as.polySpline(object, ...)
```

**Arguments**

- `object` An object that inherits from class `spline`.  
`...` Optional additional arguments. At present no additional arguments are used.

**Value**

An object that inherits from class `polySpline`. This is the piecewise polynomial representation of a univariate spline function. It is defined by a set of distinct numeric values called knots. The spline function is a polynomial function between each successive pair of knots. At each interior knot the polynomial segments on each side are constrained to have the same value of the function and some of its derivatives.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

[interpSpline](#), [periodicSpline](#), [splineKnots](#), [splineOrder](#)

**Examples**

```
require(graphics)
ispl <- polySpline(interpSpline(weight ~ height, women, bSpline = TRUE))
print(ispl) # print the piecewise polynomial representation
plot(ispl) # plots over the range of the knots
points(women$height, women$weight)
```

***predict.bs***

*Evaluate a Spline Basis*

**Description**

Evaluate a predefined spline basis at given values.

**Usage**

```
S3 method for class bs
predict(object, newx, ...)

S3 method for class ns
predict(object, newx, ...)
```

**Arguments**

- `object` the result of a call to `bs` or `ns` having attributes describing knots, degree, etc.  
`newx` the `x` values at which evaluations are required.  
`...` Optional additional arguments. At present no additional arguments are used.

### Value

An object just like object, except evaluated at the new values of x.

These are methods for the generic function [predict](#) for objects inheriting from classes "bs" or "ns". See [predict](#) for the general behavior of this function.

### See Also

[bs](#), [ns](#), [poly](#).

### Examples

```
require(stats)
basis <- ns(women$height, df = 5)
newX <- seq(58, 72, length.out = 51)
evaluate the basis at the new data
predict(basis, newX)
```

**predict.bSpline**      *Evaluate a Spline at New Values of x*

### Description

The predict methods for the classes that inherit from the virtual classes `bSpline` and `polySpline` are used to evaluate the spline or its derivatives. The plot method for a spline object first evaluates predict with the `x` argument missing, then plots the resulting `xyVector` with `type = "l"`.

### Usage

```
S3 method for class bSpline
predict(object, x, nseg = 50, deriv = 0, ...)
S3 method for class nbSpline
predict(object, x, nseg = 50, deriv = 0, ...)
S3 method for class pbSpline
predict(object, x, nseg = 50, deriv = 0, ...)
S3 method for class npolySpline
predict(object, x, nseg = 50, deriv = 0, ...)
S3 method for class ppolySpline
predict(object, x, nseg = 50, deriv = 0, ...)
```

### Arguments

|                     |                                                                                                                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | An object that inherits from the <code>bSpline</code> or the <code>polySpline</code> class.                                                                                                                    |
| <code>x</code>      | A numeric vector of x values at which to evaluate the spline. If this argument is missing a suitable set of x values is generated as a sequence of <code>nseg</code> segments spanning the range of the knots. |
| <code>nseg</code>   | A positive integer giving the number of segments in a set of equally-spaced x values spanning the range of the knots in <code>object</code> . This value is only used if <code>x</code> is missing.            |
| <code>deriv</code>  | An integer between 0 and <code>splineOrder(object) - 1</code> specifying the derivative to evaluate.                                                                                                           |
| <code>...</code>    | further arguments passed to or from other methods.                                                                                                                                                             |

**Value**

an `xyVector` with components

- `x` the supplied or inferred numeric vector of `x` values
- `y` the value of the spline (or its `deriv`'th derivative) at the `x` vector

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

[xyVector](#), [interpSpline](#), [periodicSpline](#)

**Examples**

```
require(graphics); require(stats)
ispl <- interpSpline(weight ~ height, women)
opar <- par(mfrow = c(2, 2), las = 1)
plot(predict(ispl, nseg = 201), # plots over the range of the knots
 main = "Original data with interpolating spline", type = "l",
 xlab = "height", ylab = "weight")
points(women$height, women$weight, col = 4)
plot(predict(ispl, nseg = 201, deriv = 1),
 main = "First derivative of interpolating spline", type = "l",
 xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 201, deriv = 2),
 main = "Second derivative of interpolating spline", type = "l",
 xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 401, deriv = 3),
 main = "Third derivative of interpolating spline", type = "l",
 xlab = "height", ylab = "weight")
par(opar)
```

**Description**

Evaluate the design matrix for the B-splines defined by knots at the values in `x`.

**Usage**

```
splineDesign(knots, x, ord = 4, derivs, outer.ok = FALSE,
 sparse = FALSE)
spline.des (knots, x, ord = 4, derivs, outer.ok = FALSE,
 sparse = FALSE)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>knots</code>    | a numeric vector of knot positions with non-decreasing values.                                                                                                                                                                                                    |
| <code>x</code>        | a numeric vector of values at which to evaluate the B-spline functions or derivatives. Unless <code>outer.ok</code> is true, the values in <code>x</code> must be between <code>knots[ord]</code> and <code>knots[ length(knots) + 1 - ord ]</code> .             |
| <code>ord</code>      | a positive integer giving the order of the spline function. This is the number of coefficients in each piecewise polynomial segment, thus a cubic spline has order 4. Defaults to 4.                                                                              |
| <code>derivs</code>   | an integer vector of the same length as <code>x</code> and with values between 0 and <code>ord - 1</code> . The derivative of the given order is evaluated at the <code>x</code> positions. Defaults to a vector of zeroes of the same length as <code>x</code> . |
| <code>outer.ok</code> | logical indicating if <code>x</code> should be allowed outside the <i>inner</i> knots, see the <code>x</code> argument.                                                                                                                                           |
| <code>sparse</code>   | logical indicating if the result should inherit from class <code>sparseMatrix</code> (package <code>Matrix</code> ).                                                                                                                                              |

### Value

A matrix with `length( x )` rows and `length( knots ) - ord` columns. The *i*'th row of the matrix contains the coefficients of the B-splines (or the indicated derivative of the B-splines) defined by the knot vector and evaluated at the *i*'th value of `x`. Each B-spline is defined by a set of `ord` successive knots so the total number of B-splines is `length(knots)-ord`.

### Note

The older `spline.des` function takes the same arguments but returns a list with several components including `knots`, `ord`, `derivs`, and `design`. The `design` component is the same as the value of the `splineDesign` function.

### Author(s)

Douglas Bates and Bill Venables

### Examples

```
require(graphics)
splineDesign(knots = 1:10, x = 4:7)
visualize band structure
Matrix::drop0(zapsmall(6*splineDesign(knots = 1:40, x = 4:37, sparse = TRUE)))

knots <- c(1,1.8,3:5,6.5,7,8.1,9.2,10) # 10 => 10-4 = 6 Basis splines
x <- seq(min(knots)-1, max(knots)+1, length.out = 501)
bb <- splineDesign(knots, x = x, outer.ok = TRUE)

plot(range(x), c(0,1), type = "n", xlab = "x", ylab = "",
 main = "B-splines - sum to 1 inside inner knots")
mtext(expression(B[j](x) * and "* sum(B[j](x), j == 1, 6)), adj = 0)
abline(v = knots, lty = 3, col = "light gray")
abline(v = knots[c(4,length(knots)-3)], lty = 3, col = "gray10")
lines(x, rowSums(bb), col = "gray", lwd = 2)
matlines(x, bb, ylim = c(0,1), lty = 1)
```

**splineKnots** *Knot Vector from a Spline*

### Description

Return the knot vector corresponding to a spline object.

### Usage

```
splineKnots(object)
```

### Arguments

|        |                                              |
|--------|----------------------------------------------|
| object | an object that inherits from class "spline". |
|--------|----------------------------------------------|

### Value

A non-decreasing numeric vector of knot positions.

### Author(s)

Douglas Bates and Bill Venables

### Examples

```
ispl <- interpSpline(weight ~ height, women)
splineKnots(ispl)
```

**splineOrder** *Determine the Order of a Spline*

### Description

Return the order of a spline object.

### Usage

```
splineOrder(object)
```

### Arguments

|        |                                              |
|--------|----------------------------------------------|
| object | An object that inherits from class "spline". |
|--------|----------------------------------------------|

### Details

The order of a spline is the number of coefficients in each piece of the piecewise polynomial representation. Thus a cubic spline has order 4.

### Value

A positive integer.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

**Examples**

```
splineOrder(interpSpline(weight ~ height, women))
```

---

xyVector

*Construct an xyVector Object*

---

**Description**

Create an object to represent a set of x-y pairs. The resulting object can be treated as a matrix or as a data frame or as a vector. When treated as a vector it reduces to the y component only.

The result of functions such as `predict.spline` is returned as an `xyVector` object so the x-values used to generate the y-positions are retained, say for purposes of generating plots.

**Usage**

```
xyVector(x, y)
```

**Arguments**

|   |                                          |
|---|------------------------------------------|
| x | a numeric vector                         |
| y | a numeric vector of the same length as x |

**Value**

An object of class `xyVector` with components

|   |                                          |
|---|------------------------------------------|
| x | a numeric vector                         |
| y | a numeric vector of the same length as x |

**Author(s)**

Douglas Bates and Bill Venables

**Examples**

```
require(stats); require(graphics)
ispl <- interpSpline(weight ~ height, women)
weights <- predict(ispl, seq(55, 75, length.out = 51))
class(weights)
plot(weights, type = "l", xlab = "height", ylab = "weight")
points(women$height, women$weight)
weights
```

`.checkMFClasses`      *Functions to Check the Type of Variables passed to Model Frames*

---

### Description

`.checkMFClasses` checks if the variables used in a predict method agree in type with those used for fitting.

`.MFclass` categorizes variables for this purpose.

### Usage

```
.checkMFClasses(cl, m, ordNotOK = FALSE)
.MFclass(x)
.getXlevels(Terms, m)
```

## Arguments

|          |                                                    |
|----------|----------------------------------------------------|
| c1       | a character vector of class descriptions to match. |
| m        | a model frame.                                     |
| x        | any R object.                                      |
| ordNotOK | logical: are ordered factors different?            |
| Terms    | a terms object.                                    |

## Details

For applications involving `model.matrix` such as linear models we do not need to differentiate between ordered factors and factors as although these affect the coding, the coding used in the fit is already recorded and imposed during prediction. However, other applications may treat ordered factors differently: `rpart` does, for example.

## Value

- .MFclass returns a character string, one of "logical", "ordered", "factor", "numeric", "nmatrix.\*" (a numeric matrix with a number of columns appended) or "other".
- .getXlevels returns a named character vector, or NULL.

## Description

The function `acf` computes (and by default plots) estimates of the autocovariance or autocorrelation function. Function `pacf` is the function used for the partial autocorrelations. Function `ccf` computes the cross-correlation or cross-covariance of two univariate series.

## Usage

```
acf(x, lag.max = NULL,
 type = c("correlation", "covariance", "partial"),
 plot = TRUE, na.action = na.fail, demean = TRUE, ...)

pacf(x, lag.max, plot, na.action, ...)

Default S3 method:
pacf(x, lag.max = NULL, plot = TRUE, na.action = na.fail,
 ...)

ccf(x, y, lag.max = NULL, type = c("correlation", "covariance"),
 plot = TRUE, na.action = na.fail, ...)

S3 method for class acf
x[i, j]
```

### Arguments

|           |                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y      | a univariate or multivariate (not ccf) numeric time series object or a numeric vector or matrix, or an "acf" object.                                                                                                                     |
| lag.max   | maximum lag at which to calculate the acf. Default is $10 \log_{10}(N/m)$ where $N$ is the number of observations and $m$ the number of series. Will be automatically limited to one less than the number of observations in the series. |
| type      | character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial".                                                                                                       |
| plot      | logical. If TRUE (the default) the acf is plotted.                                                                                                                                                                                       |
| na.action | function to be called to handle missing values. na.pass can be used.                                                                                                                                                                     |
| demean    | logical. Should the covariances be about the sample means?                                                                                                                                                                               |
| ...       | further arguments to be passed to plot.acf.                                                                                                                                                                                              |
| i         | a set of lags (time differences) to retain.                                                                                                                                                                                              |
| j         | a set of series (names or numbers) to retain.                                                                                                                                                                                            |

### Details

For type = "correlation" and "covariance", the estimates are based on the sample covariance. (The lag 0 autocorrelation is fixed at 1 by convention.)

By default, no missing values are allowed. If the na.action function passes through missing values (as na.pass does), the covariances are computed from the complete cases. This means that the estimate computed may well not be a valid autocorrelation sequence, and may contain missing values. Missing values are not allowed when computing the PACF of a multivariate time series.

The partial correlation coefficient is estimated by fitting autoregressive models of successively higher orders up to lag.max.

The generic function plot has a method for objects of class "acf".

The lag is returned and plotted in units of time, and not numbers of observations.

There are print and subsetting methods for objects of class "acf".

### Value

An object of class "acf", which is a list with the following elements:

|        |                                                                              |
|--------|------------------------------------------------------------------------------|
| lag    | A three dimensional array containing the lags at which the acf is estimated. |
| acf    | An array with the same dimensions as lag containing the estimated acf.       |
| type   | The type of correlation (same as the type argument).                         |
| n.used | The number of observations in the time series.                               |
| series | The name of the series x.                                                    |
| snames | The series names for a multivariate time series.                             |

The lag k value returned by ccf(x, y) estimates the correlation between x[t+k] and y[t].

The result is returned invisibly if plot is TRUE.

acf2AR

*Compute an AR Process Exactly Fitting an ACF*

## Description

Compute an AR process exactly fitting an autocorrelation function.

## Usage

```
acf2AR(acf)
```

## Arguments

|     |                                                |
|-----|------------------------------------------------|
| acf | An autocorrelation or autocovariance sequence. |
|-----|------------------------------------------------|

## Value

A matrix, with one row for the computed AR( $p$ ) coefficients for  $1 \leq p \leq \text{length}(acf)$ .

## See Also

[ARMAacf](#), [ar.yw](#) which does this from an empirical ACF.

## Examples

```
(Acf <- ARMAacf(c(0.6, 0.3, -0.2)))
acf2AR(Acf)
```

add1

*Add or Drop All Possible Single Terms to a Model*

## Description

Compute all the single terms in the scope argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

## Usage

```
add1(object, scope, ...)

Default S3 method:
add1(object, scope, scale = 0, test = c("none", "Chisq"),
 k = 2, trace = FALSE, ...)

S3 method for class lm
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),
 x = NULL, k = 2, ...)

S3 method for class glm
add1(object, scope, scale = 0,
 test = c("none", "Rao", "LRT", "Chisq", "F"),
 x = NULL, k = 2, ...)

drop1(object, scope, ...)

Default S3 method:
drop1(object, scope, scale = 0, test = c("none", "Chisq"),
 k = 2, trace = FALSE, ...)

S3 method for class lm
drop1(object, scope, scale = 0, all.cols = TRUE,
 test = c("none", "Chisq", "F"), k = 2, ...)

S3 method for class glm
drop1(object, scope, scale = 0,
 test = c("none", "Rao", "LRT", "Chisq", "F"),
 k = 2, ...)
```

## Arguments

- |        |                                                                                               |
|--------|-----------------------------------------------------------------------------------------------|
| object | a fitted model object.                                                                        |
| scope  | a formula giving the terms to be considered for adding or dropping.                           |
| scale  | an estimate of the residual mean square to be used in computing $C_p$ . Ignored if 0 or NULL. |

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| test     | should the results include a test statistic relative to the original model? The F test is only appropriate for <a href="#">lm</a> and <a href="#">aov</a> models or perhaps for <a href="#">glm</a> fits with estimated dispersion. The $\chi^2$ test can be an exact test ( <a href="#">lm</a> models with known scale) or a likelihood-ratio test or a test of the reduction in scaled deviance depending on the method. For <a href="#">glm</a> fits, you can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution). |
| k        | the penalty constant in AIC / $C_p$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| trace    | if TRUE, print out progress reports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| x        | a model matrix containing columns for the fitted model and all terms in the upper scope. Useful if add1 is to be called repeatedly. <b>Warning:</b> no checks are done on its validity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| all.cols | (Provided for compatibility with S.) Logical to specify whether all columns of the design matrix should be used. If FALSE then non-estimable columns are dropped, but the result is not usually statistically meaningful.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| ...      | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

For drop1 methods, a missing scope is taken to be all terms in the model. The hierarchy is respected when considering terms to be added or dropped: all main effects contained in a second-order interaction must remain, and so on.

In a scope formula . means 'what is already there'.

The methods for [lm](#) and [glm](#) are more efficient in that they do not recompute the model matrix and call the [fit](#) methods directly.

The default output table gives AIC, defined as minus twice log likelihood plus  $2p$  where  $p$  is the rank of the model (the number of effective parameters). This is only defined up to an additive constant (like log-likelihoods). For linear Gaussian models with fixed scale, the constant is chosen to give Mallows'  $C_p$ ,  $RSS/scale + 2p - n$ . Where  $C_p$  is used, the column is labelled as Cp rather than AIC.

The F tests for the "glm" methods are based on analysis of deviance tests, so if the dispersion is estimated it is based on the residual deviance, unlike the F tests of [anova.glm](#).

## Value

An object of class "anova" summarizing the differences in fit between the models.

## Warning

The model fitting must apply the models to the same dataset. Most methods will attempt to use a subset of the data with no missing values for any of the variables if `na.action = na.omit`, but this may give biased results. Only use these functions with data containing missing values with great care.

The default methods make calls to the function [nobs](#) to check that the number of observations involved in the fitting process remained unchanged.

**Note**

These are not fully equivalent to the functions in S. There is no `keep` argument, and the methods used are not quite so computationally efficient.

Their authors' definitions of Mallows'  $C_p$  and Akaike's AIC are used, not those of the authors of the models chapter of S.

**Author(s)**

The design was inspired by the S functions of the same names described in Chambers (1992).

**Examples**

```
require(graphics); require(utils)
following example(swiss)
lm1 <- lm(Fertility ~ ., data = swiss)
add1(lm1, ~ I(Education^2) + .^2)
drop1(lm1, test = "F") # So called type II anova

following example(glm)

drop1(glm.D93, test = "Chisq")
drop1(glm.D93, test = "F")
add1(glm.D93, scope = ~outcome*treatment, test = "Rao") ## Pearson Chi-square
```

**Description**

For a given table one can specify which of the classifying factors to expand by one or more levels to hold margins to be calculated. One may for example form sums and means over the first dimension and medians over the second. The resulting table will then have two extra levels for the first dimension and one extra level for the second. The default is to sum over all margins in the table. Other possibilities may give results that depend on the order in which the margins are computed. This is flagged in the printed output from the function.

**Usage**

```
addmargins(A, margin = seq_along(dim(A)), FUN = sum, quiet = FALSE)
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A      | table or array. The function uses the presence of the "dim" and "dimnames" attributes of A.                                                                                                                                                                                                                                 |
| margin | vector of dimensions over which to form margins. Margins are formed in the order in which dimensions are specified in margin.                                                                                                                                                                                               |
| FUN    | list of the same length as margin, each element of the list being either a function or a list of functions. Names of the list elements will appear as levels in dimnames of the result. Unnamed list elements will have names constructed: the name of a function or a constructed name based on the position in the table. |
| quiet  | logical which suppresses the message telling the order in which the margins were computed.                                                                                                                                                                                                                                  |

## Details

If the functions used to form margins are not commutative the result depends on the order in which margins are computed. Annotation of margins is done via naming the FUN list.

## Value

A table or array with the same number of dimensions as A, but with extra levels of the dimensions mentioned in margin. The number of levels added to each dimension is the length of the entries in FUN. A message with the order of computation of margins is printed.

## Author(s)

Bendix Carstensen, Steno Diabetes Center & Department of Biostatistics, University of Copenhagen, <http://www.biostat.ku.dk/~bxc>, autumn 2003. Margin naming enhanced by Duncan Murdoch.

[table](#), [ftable](#), [margin.table](#).

## Examples

```

Aye <- sample(c("Yes", "Si", "Oui"), 177, replace = TRUE)
Bee <- sample(c("Hum", "Buzz"), 177, replace = TRUE)
Sea <- sample(c("White", "Black", "Red", "Dead"), 177, replace = TRUE)
(A <- table(Aye, Bee, Sea))
addmargins(A)

ftable(A)
ftable(addmargins(A))

Non-commutative functions - note differences between resulting tables:
ftable(addmargins(A, c(1, 3),
 FUN = list(Sum = sum, list(Min = min, Max = max))))
ftable(addmargins(A, c(3, 1),
 FUN = list(list(Min = min, Max = max), Sum = sum)))

Weird function needed to return the N when computing percentages
sqsm <- function(x) sum(x)^2/100
B <- table(Sea, Bee)
round(sweep(addmargins(B, 1, list(list(All = sum, N = sqsm))), 2,

```

```

apply(B, 2, sum)/100, "/"), 1)
round(sweep(addmargins(B, 2, list(list(All = sum, N = sqsm))), 1,
 apply(B, 1, sum)/100, "/"), 1)

A total over Bee requires formation of the Bee-margin first:
mB <- addmargins(B, 2, FUN = list(list(Total = sum)))
round(ftable(sweep(addmargins(mB, 1, list(list(All = sum, N = sqsm))), 2,
 apply(mB, 2, sum)/100, "/")), 1)

Zero.Printing table+Margins:
set.seed(1)
x <- sample(1:7, 20, replace = TRUE)
y <- sample(1:7, 20, replace = TRUE)
tx <- addmargins(table(x, y))
print(tx, zero.print = ".")

```

**aggregate***Compute Summary Statistics of Data Subsets***Description**

Splits the data into subsets, computes summary statistics for each, and returns the result in a convenient form.

**Usage**

```

aggregate(x, ...)

Default S3 method:
aggregate(x, ...)

S3 method for class data.frame
aggregate(x, by, FUN, ..., simplify = TRUE)

S3 method for class formula
aggregate(formula, data, FUN, ...,
 subset, na.action = na.omit)

S3 method for class ts
aggregate(x, nfrequency = 1, FUN = sum, ndeltat = 1,
 ts.eps = getOption("ts.eps"), ...)

```

**Arguments**

- |                 |                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>        | an R object.                                                                                                                               |
| <b>by</b>       | a list of grouping elements, each as long as the variables in the data frame <b>x</b> .<br>The elements are coerced to factors before use. |
| <b>FUN</b>      | a function to compute the summary statistics which can be applied to all data subsets.                                                     |
| <b>simplify</b> | a logical indicating whether results should be simplified to a vector or matrix if possible.                                               |

|            |                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula    | a <a href="#">formula</a> , such as $y \sim x$ or <code>cbind(y1, y2) ~ x1 + x2</code> , where the $y$ variables are numeric data to be split into groups according to the grouping $x$ variables (usually factors). |
| data       | a data frame (or list) from which the variables in formula should be taken.                                                                                                                                          |
| subset     | an optional vector specifying a subset of observations to be used.                                                                                                                                                   |
| na.action  | a function which indicates what should happen when the data contain NA values. The default is to ignore missing values in the given variables.                                                                       |
| nfrequency | new number of observations per unit of time; must be a divisor of the frequency of $x$ .                                                                                                                             |
| ndeltat    | new fraction of the sampling period between successive observations; must be a divisor of the sampling interval of $x$ .                                                                                             |
| ts.eps     | tolerance used to decide if nfrequency is a sub-multiple of the original frequency.                                                                                                                                  |
| ...        | further arguments passed to or used by methods.                                                                                                                                                                      |

## Details

`aggregate` is a generic function with methods for data frames and time series.

The default method, `aggregate.default`, uses the time series method if  $x$  is a time series, and otherwise coerces  $x$  to a data frame and calls the data frame method.

`aggregate.data.frame` is the data frame method. If  $x$  is not a data frame, it is coerced to one, which must have a non-zero number of rows. Then, each of the variables (columns) in  $x$  is split into subsets of cases (rows) of identical combinations of the components of `by`, and `FUN` is applied to each such subset with further arguments in `...` passed to it. The result is reformatted into a data frame containing the variables in `by` and  $x$ . The ones arising from `by` contain the unique combinations of grouping values used for determining the subsets, and the ones arising from  $x$  the corresponding summaries for the subset of the respective variables in  $x$ . If `simplify` is true, summaries are simplified to vectors or matrices if they have a common length of one or greater than one, respectively; otherwise, lists of summary results according to subsets are obtained. Rows with missing values in any of the `by` variables will be omitted from the result. (Note that versions of R prior to 2.11.0 required `FUN` to be a scalar function.)

`aggregate.formula` is a standard formula interface to `aggregate.data.frame`.

`aggregate.ts` is the time series method, and requires `FUN` to be a scalar function. If  $x$  is not a time series, it is coerced to one. Then, the variables in  $x$  are split into appropriate blocks of length `frequency(x)` / `nfrequency`, and `FUN` is applied to each such block, with further (named) arguments in `...` passed to it. The result returned is a time series with frequency `nfrequency` holding the aggregated values. Note that this make most sense for a quarterly or yearly result when the original series covers a whole number of quarters or years: in particular aggregating a monthly series to quarters starting in February does not give a conventional quarterly series.

`FUN` is passed to [match.fun](#), and hence it can be a function or a symbol or character string naming a function.

## Value

For the time series method, a time series of class "ts" or class c("mts", "ts").

For the data frame method, a data frame with columns corresponding to the grouping variables in `by` followed by aggregated columns from  $x$ . If the `by` has names, the non-empty times are used to label the columns in the results, with unnamed grouping variables being named `Group.i` for `by[[i]]`.

**Examples**

```
Compute the averages for the variables in state.x77, grouped
according to the region (Northeast, South, North Central, West) that
each state belongs to.
aggregate(state.x77, list(Region = state.region), mean)

Compute the averages according to region and the occurrence of more
than 130 days of frost.
aggregate(state.x77,
 list(Region = state.region,
 Cold = state.x77[,"Frost"] > 130),
 mean)
(Note that no state in South is THAT cold.)

example with character variables and NAs
testDF <- data.frame(v1 = c(1,3,5,7,8,3,5,NA,4,5,7,9),
 v2 = c(11,33,55,77,88,33,55,NA,44,55,77,99))
by1 <- c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12)
by2 <- c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA)
aggregate(x = testDF, by = list(by1, by2), FUN = "mean")

and if you want to treat NAs as a group
fby1 <- factor(by1, exclude = "")
fby2 <- factor(by2, exclude = "")
aggregate(x = testDF, by = list(fby1, fby2), FUN = "mean")

Formulas, one ~ one, one ~ many, many ~ one, and many ~ many:
aggregate(weight ~ feed, data = chickwts, mean)
aggregate(breaks ~ wool + tension, data = warpbreaks, mean)
aggregate(cbind(Ozone, Temp) ~ Month, data = airquality, mean)
aggregate(cbind(ncases, ncontrols) ~ alcgp + tobgp, data = esoph, sum)

Dot notation:
aggregate(. ~ Species, data = iris, mean)
aggregate(len ~ ., data = ToothGrowth, mean)

Often followed by xtabs():
ag <- aggregate(len ~ ., data = ToothGrowth, mean)
xtabs(len ~ ., data = ag)
```

```
Compute the average annual approval ratings for American presidents.
aggregate(presidents, nfrequency = 1, FUN = mean)
Give the summer less weight.
aggregate(presidents, nfrequency = 1,
 FUN = weighted.mean, w = c(1, 1, 0.5, 1))
```

**AIC***Akaike's An Information Criterion***Description**

Generic function calculating Akaike's 'An Information Criterion' for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula  $-2\log\text{likelihood} + kn_{par}$ , where  $n_{par}$  represents the number of parameters in the fitted model, and  $k = 2$  for the usual AIC, or  $k = \log(n)$  ( $n$  being the number of observations) for the so-called BIC or SBC (Schwarz's Bayesian criterion).

**Usage**

```
AIC(object, ..., k = 2)

BIC(object, ...)
```

**Arguments**

- |        |                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | a fitted model object for which there exists a <code>logLik</code> method to extract the corresponding log-likelihood, or an object inheriting from class <code>logLik</code> . |
| ...    | optionally more fitted model objects.                                                                                                                                           |
| k      | numeric, the <i>penalty</i> per parameter to be used; the default <code>k = 2</code> is the classical AIC.                                                                      |

**Details**

When comparing models fitted by maximum likelihood to the same data, the smaller the AIC or BIC, the better the fit.

The theory of AIC requires that the log-likelihood has been maximized: whereas AIC can be computed for models not fitted by maximum likelihood, their AIC values should not be compared.

Examples of models not 'fitted to the same data' are where the response is transformed (accelerated-life models are fitted to log-times) and where contingency tables have been used to summarize data.

These are generic functions (with S4 generics defined in package `stats4`): however methods should be defined for the log-likelihood function `logLik` rather than these functions: the action of their default methods is to call `logLik` on all the supplied objects and assemble the results. Note that in several common cases `logLik` does not return the value at the MLE: see its help page.

The log-likelihood and hence the AIC/BIC is only defined up to an additive constant. Different constants have conventionally been used for different purposes and so `extractAIC` and AIC may give different values (and do for models of class "`lm`": see the help for `extractAIC`). Particular care is needed when comparing fits of different classes (with, for example, a comparison of a Poisson and gamma GLM being meaningless since one has a discrete response, the other continuous).

BIC is defined as `AIC(object, ..., k = log(nobs(object)))`. This needs the number of observations to be known: the default method looks first for a "nobs" attribute on the return value from the `logLik` method, then tries the `nobs` generic, and if neither succeed returns BIC as NA.

**Value**

If just one object is provided, a numeric value with the corresponding AIC (or BIC, or ..., depending on k).

If multiple objects are provided, a `data.frame` with rows corresponding to the objects and columns representing the number of parameters in the model (df) and the AIC or BIC.

**Examples**

```
lm1 <- lm(Fertility ~ . , data = swiss)
AIC(lm1)
stopifnot(all.equal(AIC(lm1),
 AIC(logLik(lm1))))
BIC(lm1)

lm2 <- update(lm1, . ~ . -Examination)
AIC(lm1, lm2)
BIC(lm1, lm2)
```

---

alias

*Find Aliases (Dependencies) in a Model*

---

**Description**

Find aliases (linearly dependent terms) in a linear model specified by a formula.

**Usage**

```
alias(object, ...)

S3 method for class formula
alias(object, data, ...)

S3 method for class lm
alias(object, complete = TRUE, partial = FALSE,
 partial.pattern = FALSE, ...)
```

### Arguments

|                 |                                                                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object          | A fitted model object, for example from <code>lm</code> or <code>aov</code> , or a formula for <code>alias.formula</code> .                                                |
| data            | Optionally, a data frame to search for the objects in the formula.                                                                                                         |
| complete        | Should information on complete aliasing be included?                                                                                                                       |
| partial         | Should information on partial aliasing be included?                                                                                                                        |
| partial.pattern | Should partial aliasing be presented in a schematic way? If this is done, the results are presented in a more compact way, usually giving the deciles of the coefficients. |
| ...             | further arguments passed to or from other methods.                                                                                                                         |

### Details

Although the main method is for class "`lm`", `alias` is most useful for experimental designs and so is used with fits from `aov`. Complete aliasing refers to effects in linear models that cannot be estimated independently of the terms which occur earlier in the model and so have their coefficients omitted from the fit. Partial aliasing refers to effects that can be estimated less precisely because of correlations induced by the design.

Some parts of the "`lm`" method require recommended package **MASS** to be installed.

### Value

A list (of `class "listof"`) containing components

|          |                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Model    | Description of the model; usually the formula.                                                                                                           |
| Complete | A matrix with columns corresponding to effects that are linearly dependent on the rows.                                                                  |
| Partial  | The correlations of the estimable effects, with a zero diagonal. An object of class " <code>mtable</code> " which has its own <code>print</code> method. |

### Note

The aliasing pattern may depend on the contrasts in use: Helmert contrasts are probably most useful. The defaults are different from those in S.

### Author(s)

The design was inspired by the S function of the same name described in Chambers *et al.* (1992).

### References

Chambers, J. M., Freeny, A and Heiberger, R. M. (1992) *Analysis of variance; designed experiments*. Chapter 5 of *Statistical Models in S* eds J. M. Chambers and T. J. Hastie, Wadsworth & Brooks/Cole.

### Examples

```
op <- options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
alias(npk.aov)
options(op) # reset
```

---

**anova***Anova Tables*

---

**Description**

Compute analysis of variance (or deviance) tables for one or more fitted model objects.

**Usage**

```
anova(object, ...)
```

**Arguments**

- |        |                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------|
| object | an object containing the results returned by a model fitting function (e.g., <code>lm</code> or <code>glm</code> ). |
| ...    | additional objects of the same type.                                                                                |

**Value**

This (generic) function returns an object of class `anova`. These objects represent analysis-of-variance and analysis-of-deviance tables. When given a single argument it produces a table which tests whether the model terms are significant.

When given a sequence of objects, `anova` tests the models against one another in the order specified.

The print method for `anova` objects prints tables in a ‘pretty’ form.

**Warning**

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used.

---

**anova.glm***Analysis of Deviance for Generalized Linear Model Fits*

---

**Description**

Compute an analysis of deviance table for one or more generalized linear model fits.

**Usage**

```
S3 method for class glm
anova(object, ..., dispersion = NULL, test = NULL)
```

### Arguments

|             |                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| object, ... | objects of class <code>glm</code> , typically the result of a call to <code>glm</code> , or a list of objects for the "glmlist" method. |
| dispersion  | the dispersion parameter for the fitting family. By default it is obtained from the object(s).                                          |
| test        | a character string, (partially) matching one of "Chisq", "LRT", "Rao", "F" or "Cp". See <code>stat.anova</code> .                       |

### Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. For models with known dispersion (e.g., binomial and Poisson fits) the chi-squared test is most appropriate, and for those with dispersion estimated by moments (e.g., `gaussian`, `quasibinomial` and `quasipoisson` fits) the F test is most appropriate. Mallows'  $C_p$  statistic is the residual deviance plus twice the estimate of  $\sigma^2$  times the residual degrees of freedom, which is closely related to AIC (and a multiple of it if the dispersion is known). You can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).

The dispersion estimate will be taken from the largest model, using the value returned by `summary.glm`. As this will in most cases use a Chi-squared-based estimate, the F tests are not based on the residual deviance in the analysis of deviance table shown.

### Value

An object of class "anova" inheriting from class "data.frame".

### Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used, and `anova` will detect this with an error.

`glm`, `anova`.

`drop1` for so-called 'type II' anova where each term is dropped one at a time respecting their hierarchy.

## Examples

```
#> --- Continuing the Example from ?glm:
#>
#> anova(glm.D93)
#> anova(glm.D93, test = "Cp")
#> anova(glm.D93, test = "Chisq")
#> glm.D93a <- update(glm.D93, ~treatment*outcome) # equivalent to Pearson Chi-square
#> anova(glm.D93, glm.D93a, test = "Rao")
```

anova.lm

*ANOVA for Linear Model Fits*

## Description

Compute an analysis of variance table for one or more linear model fits.

## Usage

```
S3 method for class lm
anova(object, ...)

S3 method for class lmlist
anova(object, ..., scale = 0, test = "F")
```

## Arguments

- |             |                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object, ... | objects of class <code>lm</code> , usually, a result of a call to <code>lm</code> .                                                                               |
| test        | a character string specifying the test statistic to be used. Can be one of "F", "Chisq" or "Cp", with partial matching allowed, or <code>NULL</code> for no test. |
| scale       | numeric. An estimate of the noise variance $\sigma^2$ . If zero this will be estimated from the largest model considered.                                         |

## Details

Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in as the rows of a table, plus the residual sum of squares.

The table will contain F statistics (and P values) comparing the mean square for the row to the residual mean square.

If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If `scale` is specified chi-squared tests can be used. Mallows'  $C_p$  statistic is the residual sum of squares plus twice the estimate of  $\sigma^2$  times the residual degrees of freedom.

**Value**

An object of class "anova" inheriting from class "data.frame".

**Warning**

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used, and `anova.lmList` will detect this with an error.

**See Also**

The model fitting function `lm`, `anova`.

`drop1` for so-called 'type II' anova where each term is dropped one at a time respecting their hierarchy.

**Examples**

```
sequential table
fit <- lm(sr ~ ., data = LifeCycleSavings)
anova(fit)

same effect via separate models
fit0 <- lm(sr ~ 1, data = LifeCycleSavings)
fit1 <- update(fit0, . ~ . + pop15)
fit2 <- update(fit1, . ~ . + pop75)
fit3 <- update(fit2, . ~ . + dpi)
fit4 <- update(fit3, . ~ . + ddpi)
anova(fit0, fit1, fit2, fit3, fit4, test = "F")

anova(fit4, fit2, fit0, test = "F") # unconventional order
```

**Description**

Compute a (generalized) analysis of variance table for one or more multivariate linear models.

**Usage**

```
S3 method for class mlm
anova(object, ...,
 test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy",
 "Spherical"),
 Sigma = diag(nrow = p), T = Thin.row(proj(M) - proj(X)),
 M = diag(nrow = p), X = ~0,
 idata = data.frame(index = seq_len(p)), tol = 1e-7)
```

### Arguments

|        |                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------|
| object | an object of class "mlm".                                                                              |
| ...    | further objects of class "mlm".                                                                        |
| test   | choice of test statistic (see below).                                                                  |
| Sigma  | (only relevant if <code>test == "Spherical"</code> ). Covariance matrix assumed proportional to Sigma. |
| T      | transformation matrix. By default computed from M and X.                                               |
| M      | formula or matrix describing the outer projection (see below).                                         |
| X      | formula or matrix describing the inner projection (see below).                                         |
| idata  | data frame describing intra-block design.                                                              |
| tol    | tolerance to be used in deciding if the residuals are rank-deficient: see <a href="#">qr</a> .         |

### Details

The `anova.mlm` method uses either a multivariate test statistic for the summary table, or a test based on sphericity assumptions (i.e. that the covariance is proportional to a given matrix).

For the multivariate test, Wilks' statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987). See [summary.manova](#) for further details.

For the "Spherical" test, proportionality is usually with the identity matrix but a different matrix can be specified using `Sigma`. Corrections for asphericity known as the Greenhouse–Geisser, respectively Huynh–Feldt, epsilons are given and adjusted *F* tests are performed.

It is common to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A transformation matrix `T` can be given directly or specified as the difference between two projections onto the spaces spanned by `M` and `X`, which in turn can be given as matrices or as model formulas with respect to `idata` (the tests will be invariant to parametrization of the quotient space `M/X`).

As with `anova.lm`, all test statistics use the SSD matrix from the largest model considered as the (generalized) denominator.

Contrary to other `anova` methods, the intercept is not excluded from the display in the single-model case. When contrast transformations are involved, it often makes good sense to test for a zero intercept.

### Value

An object of class "anova" inheriting from class "data.frame"

### Note

The Huynh–Feldt epsilon differs from that calculated by SAS (as of v. 8.2) except when the DF is equal to the number of observations minus one. This is believed to be a bug in SAS, not in R.

**ansari.test**

*Ansari-Bradley Test*

**Description**

Performs the Ansari-Bradley two-sample test for a difference in scale parameters.

**Usage**

```
ansari.test(x, ...)

Default S3 method:
ansari.test(x, y,
 alternative = c("two.sided", "less", "greater"),
 exact = NULL, conf.int = FALSE, conf.level = 0.95,
```

```

 ...)

S3 method for class formula
ansari.test(formula, data, subset, na.action, ...)

```

## Arguments

|             |                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | numeric vector of data values.                                                                                                                                                                                          |
| y           | numeric vector of data values.                                                                                                                                                                                          |
| alternative | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.                                                                                      |
| exact       | a logical indicating whether an exact p-value should be computed.                                                                                                                                                       |
| conf.int    | a logical, indicating whether a confidence interval should be computed.                                                                                                                                                 |
| conf.level  | confidence level of the interval.                                                                                                                                                                                       |
| formula     | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.                         |
| data        | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| subset      | an optional vector specifying a subset of observations to be used.                                                                                                                                                      |
| na.action   | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                              |
| ...         | further arguments to be passed to or from methods.                                                                                                                                                                      |

## Details

Suppose that `x` and `y` are independent samples from distributions with densities  $f((t - m)/s)/s$  and  $f(t - m)$ , respectively, where  $m$  is an unknown nuisance parameter and  $s$ , the ratio of scales, is the parameter of interest. The Ansari-Bradley test is used for testing the null that  $s$  equals 1, the two-sided alternative being that  $s \neq 1$  (the distributions differ only in variance), and the one-sided alternatives being  $s > 1$  (the distribution underlying `x` has a larger variance, "greater") or  $s < 1$  ("less").

By default (if `exact` is not specified), an exact p-value is computed if both samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally, a nonparametric confidence interval and an estimator for  $s$  are computed. If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

Note that mid-ranks are used in the case of ties rather than average scores as employed in Hollander & Wolfe (1973). See, e.g., Hajek, Sidak and Sen (1999), pages 131ff, for more information.

## Value

A list with class "htest" containing the following components:

|             |                                                           |
|-------------|-----------------------------------------------------------|
| statistic   | the value of the Ansari-Bradley test statistic.           |
| p.value     | the p-value of the test.                                  |
| null.value  | the ratio of scales $s$ under the null, 1.                |
| alternative | a character string describing the alternative hypothesis. |

|           |                                                                                            |
|-----------|--------------------------------------------------------------------------------------------|
| method    | the string "Ansari-Bradley test".                                                          |
| data.name | a character string giving the names of the data.                                           |
| conf.int  | a confidence interval for the scale parameter. (Only present if argument conf.int = TRUE.) |
| estimate  | an estimate of the ratio of scales. (Only present if argument conf.int = TRUE.)            |

### Note

To compare results of the Ansari-Bradley test to those of the F test to compare two variances (under the assumption of normality), observe that  $s$  is the ratio of scales and hence  $s^2$  is the ratio of variances (provided they exist), whereas for the F test the ratio of variances itself is the parameter of interest. In particular, confidence intervals are for  $s$  in the Ansari-Bradley test but for  $s^2$  in the F test.

 100, 96, 108, 103, 104, 114, 114, 113, 108, 106, 99)
ansari.test(ramsay, jung.parekh)

ansari.test(rnorm(10), rnorm(10, 0, 2), conf.int = TRUE)

try more points - failed in 2.4.1
ansari.test(rnorm(100), rnorm(100, 0, 2), conf.int = TRUE)
```

---

**aov***Fit an Analysis of Variance Model*

---

## Description

Fit an analysis of variance model by a call to `lm` for each stratum.

## Usage

```
aov(formula, data = NULL, projections = FALSE, qr = TRUE,
 contrasts = NULL, ...)
```

## Arguments

|                          |                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>     | A formula specifying the model.                                                                                                                                                                                         |
| <code>data</code>        | A data frame in which the variables specified in the formula will be found. If missing, the variables are searched for in the standard way.                                                                             |
| <code>projections</code> | Logical flag: should the projections be returned?                                                                                                                                                                       |
| <code>qr</code>          | Logical flag: should the QR decomposition be returned?                                                                                                                                                                  |
| <code>contrasts</code>   | A list of contrasts to be used for some of the factors in the formula. These are not used for any <code>Error</code> term, and supplying contrasts for factors only in the <code>Error</code> term will give a warning. |
| <code>...</code>         | Arguments to be passed to <code>lm</code> , such as <code>subset</code> or <code>na.action</code> . See ‘Details’ about <code>weights</code> .                                                                          |

## Details

This provides a wrapper to `lm` for fitting linear models to balanced or unbalanced experimental designs.

The main difference from `lm` is in the way `print`, `summary` and so on handle the fit: this is expressed in the traditional language of the analysis of variance rather than that of linear models.

If the formula contains a single `Error` term, this is used to specify error strata, and appropriate models are fitted within each error stratum.

The formula can specify multiple responses.

Weights can be specified by a `weights` argument, but should not be used with an `Error` term, and are incompletely supported (e.g., not by `model.tables`).

## Value

An object of class `c("aov", "lm")` or for multiple responses of class `c("maov", "aov", "mlm", "lm")` or for multiple error strata of class `"aovlist"`. There are `print` and `summary` methods available for these.

**Note**

`aov` is designed for balanced designs, and the results can be hard to interpret without balance: beware that missing values in the response(s) will likely lose the balance. If there are two or more error strata, the methods used are statistically inefficient without balance, and it may be better to use `lme` in package `nlme`.

Balance can be checked with the `replications` function.

The default ‘contrasts’ in R are not orthogonal contrasts, and `aov` and its helper functions will work better with such contrasts: see the examples for how to select these.

**Author(s)**

The design was inspired by the S function of the same name described in Chambers *et al.* (1992).

**References**

**Examples**

```
From Venables and Ripley (2002) p.165.

Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))
(npk.aov <- aov(yield ~ block + N*P*K, npk))
summary(npk.aov)
coefficients(npk.aov)

to show the effects of re-ordering terms contrast the two fits
aov(yield ~ block + N * P + K, npk)
aov(terms(yield ~ block + N * P + K, keep.order = TRUE), npk)

as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
npk.aovE
summary(npk.aovE)
options(op) # reset to previous
```

**Description**

Return a list of points which linearly interpolate given data points, or a function performing the linear (or constant) interpolation.

## Usage

```
approx (x, y = NULL, xout, method = "linear", n = 50,
 yleft, yright, rule = 1, f = 0, ties = mean)

approxfun(x, y = NULL, method = "linear",
 yleft, yright, rule = 1, f = 0, ties = mean)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>   | numeric vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see <a href="#">xy.coords</a> .                                                                                                                                                                                                                |
| <code>xout</code>   | an optional set of numeric values specifying where interpolation is to take place.                                                                                                                                                                                                                                                                                                  |
| <code>method</code> | specifies the interpolation method to be used. Choices are "linear" or "constant".                                                                                                                                                                                                                                                                                                  |
| <code>n</code>      | If <code>xout</code> is not specified, interpolation takes place at <code>n</code> equally spaced points spanning the interval [ <code>min(x)</code> , <code>max(x)</code> ].                                                                                                                                                                                                       |
| <code>yleft</code>  | the value to be returned when input <code>x</code> values are less than <code>min(x)</code> . The default is defined by the value of <code>rule</code> given below.                                                                                                                                                                                                                 |
| <code>yright</code> | the value to be returned when input <code>x</code> values are greater than <code>max(x)</code> . The default is defined by the value of <code>rule</code> given below.                                                                                                                                                                                                              |
| <code>rule</code>   | an integer (of length 1 or 2) describing how interpolation is to take place outside the interval [ <code>min(x)</code> , <code>max(x)</code> ]. If <code>rule</code> is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used. Use, e.g., <code>rule = 2:1</code> , if the left and right side extrapolation should differ.         |
| <code>f</code>      | for <code>method = "constant"</code> a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If <code>y0</code> and <code>y1</code> are the values to the left and right of the point then the value is <code>y0*(1-f)+y1*f</code> so that <code>f = 0</code> is right-continuous and <code>f = 1</code> is left-continuous. |
| <code>ties</code>   | Handling of tied <code>x</code> values. Either a function with a single vector argument returning a single number result or the string "ordered".                                                                                                                                                                                                                                   |

## Details

The inputs can contain missing values which are deleted, so at least two complete (`x, y`) pairs are required (for `method = "linear"`, one otherwise). If there are duplicated (tied) `x` values and `ties` is a function it is applied to the `y` values for each distinct `x` value. Useful functions in this context include `mean`, `min`, and `max`. If `ties = "ordered"` the `x` values are assumed to be already ordered. The first `y` value will be used for interpolation to the left and the last one for interpolation to the right.

## Value

`approx` returns a list with components `x` and `y`, containing `n` coordinates which interpolate the given data points according to the `method` (and `rule`) desired.

The function `approxfun` returns a function performing (linear or constant) interpolation of the given data points. For a given set of `x` values, this function will return the corresponding interpolated values. It uses data stored in its environment when it was created, the details of which are subject to change.

## Warning

The value returned by `approxfun` contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer for R >= 3.0.0.

## References

## See Also

`spline` and `splinefun` for spline interpolation.

## Examples

```
require(graphics)

x <- 1:10
y <- rnorm(10)
par(mfrow = c(2,1))
plot(x, y, main = "approx(.) and approxfun(.)")
points(approx(x, y), col = 2, pch = "*")
points(approx(x, y, method = "constant"), col = 4, pch = "*")

f <- approxfun(x, y)
curve(f(x), 0, 11, col = "green2")
points(x, y)
is.function(fc <- approxfun(x, y, method = "const")) # TRUE
curve(fc(x), 0, 10, col = "darkblue", add = TRUE)
different extrapolation on left and right side :
plot(approxfun(x, y, rule = 2:1), 0, 11,
 col = "tomato", add = TRUE, lty = 3, lwd = 2)

Show treatment of ties :

x <- c(2,2:4,4,5,5,7,7,7)
y <- c(1:6, 5:4, 3:1)
approx(x, y, xout = x)$y # warning
(ay <- approx(x, y, xout = x, ties = "ordered")$y)
stopifnot(ay == c(2,2,3,6,6,6,4,4,1,1,1))
approx(x, y, xout = x, ties = min)$y
approx(x, y, xout = x, ties = max)$y
```

## Description

Fit an autoregressive time series model to the data, by default selecting the complexity by AIC.

**Usage**

```

ar(x, aic = TRUE, order.max = NULL,
 method = c("yule-walker", "burg", "ols", "mle", "yw"),
 na.action, series, ...)

ar.burg(x, ...)
Default S3 method:
ar.burg(x, aic = TRUE, order.max = NULL,
 na.action = na.fail, demean = TRUE, series,
 var.method = 1, ...)
S3 method for class mts
ar.burg(x, aic = TRUE, order.max = NULL,
 na.action = na.fail, demean = TRUE, series,
 var.method = 1, ...)

ar.yw(x, ...)
Default S3 method:
ar.yw(x, aic = TRUE, order.max = NULL,
 na.action = na.fail, demean = TRUE, series, ...)
S3 method for class mts
ar.yw(x, aic = TRUE, order.max = NULL,
 na.action = na.fail, demean = TRUE, series,
 var.method = 1, ...)

ar.mle(x, aic = TRUE, order.max = NULL, na.action = na.fail,
 demean = TRUE, series, ...)

S3 method for class ar
predict(object, newdata, n.ahead = 1, se.fit = TRUE, ...)

```

**Arguments**

|                         |                                                                                                                                                                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | A univariate or multivariate time series.                                                                                                                                                                                                        |
| <code>aic</code>        | Logical flag. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order <code>order.max</code> is fitted.                                                              |
| <code>order.max</code>  | Maximum order (or <code>order</code> ) of model to fit. Defaults to the smaller of $N - 1$ and $10 \log_{10}(N)$ where $N$ is the number of observations except for <code>method = "mle"</code> where it is the minimum of this quantity and 12. |
| <code>method</code>     | Character string giving the method used to fit the model. Must be one of the strings in the default argument (the first few characters are sufficient). Defaults to "yule-walker".                                                               |
| <code>na.action</code>  | function to be called to handle missing values.                                                                                                                                                                                                  |
| <code>demean</code>     | should a mean be estimated during fitting?                                                                                                                                                                                                       |
| <code>series</code>     | names for the series. Defaults to <code>deparse(substitute(x))</code> .                                                                                                                                                                          |
| <code>var.method</code> | the method to estimate the innovations variance (see 'Details').                                                                                                                                                                                 |
| <code>...</code>        | additional arguments for specific methods.                                                                                                                                                                                                       |
| <code>object</code>     | a fit from <code>ar</code> .                                                                                                                                                                                                                     |
| <code>newdata</code>    | data to which to apply the prediction.                                                                                                                                                                                                           |

|                      |                                                                    |
|----------------------|--------------------------------------------------------------------|
| <code>n.ahead</code> | number of steps ahead at which to predict.                         |
| <code>se.fit</code>  | logical: return estimated standard errors of the prediction error? |

## Details

For definiteness, note that the AR coefficients have the sign in

$$x_t - \mu = a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t$$

`ar` is just a wrapper for the functions `ar.yw`, `ar.burg`, `ar.ols` and `ar.mle`.

Order selection is done by AIC if `aic` is true. This is problematic, as of the methods here only `ar.mle` performs true maximum likelihood estimation. The AIC is computed as if the variance estimate were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values. In `ar.yw` the variance matrix of the innovations is computed from the fitted coefficients and the autocovariance of `x`.

`ar.burg` allows two methods to estimate the innovations variance and hence AIC. Method 1 is to use the update given by the Levinson-Durbin recursion (Brockwell and Davis, 1991, (8.2.6) on page 242), and follows S-PLUS. Method 2 is the mean of the sum of squares of the forward and backward prediction errors (as in Brockwell and Davis, 1996, page 145). Percival and Walden (1998) discuss both. In the multivariate case the estimated coefficients will depend (slightly) on the variance estimation method.

Remember that `ar` includes by default a constant in the model, by removing the overall mean of `x` before fitting the AR model, or (`ar.mle`) estimating a constant to subtract.

## Value

For `ar` and its methods a list of class "ar" with the following elements:

|                           |                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>order</code>        | The order of the fitted model. This is chosen by minimizing the AIC if <code>aic</code> = TRUE, otherwise it is <code>order.max</code> .                                               |
| <code>ar</code>           | Estimated autoregression coefficients for the fitted model.                                                                                                                            |
| <code>var.pred</code>     | The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.                                              |
| <code>x.mean</code>       | The estimated mean of the series used in fitting and for use in prediction.                                                                                                            |
| <code>x.intercept</code>  | ( <code>ar.ols</code> only.) The intercept in the model for <code>x</code> - <code>x.mean</code> .                                                                                     |
| <code>aic</code>          | The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of -Inf.                                                                    |
| <code>n.used</code>       | The number of observations in the time series.                                                                                                                                         |
| <code>order.max</code>    | The value of the <code>order.max</code> argument.                                                                                                                                      |
| <code>partialacf</code>   | The estimate of the partial autocorrelation function up to lag <code>order.max</code> .                                                                                                |
| <code>resid</code>        | residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If <code>x</code> is a time series, so is <code>resid</code> . |
| <code>method</code>       | The value of the <code>method</code> argument.                                                                                                                                         |
| <code>series</code>       | The name(s) of the time series.                                                                                                                                                        |
| <code>frequency</code>    | The frequency of the time series.                                                                                                                                                      |
| <code>call</code>         | The matched call.                                                                                                                                                                      |
| <code>asy.var.coef</code> | (univariate case, <code>order &gt; 0</code> .) The asymptotic-theory variance matrix of the coefficient estimates.                                                                     |

For `predict.ar`, a time series of predictions, or if `se.fit` = TRUE, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

**Note**

Only the univariate case of `ar.mle` is implemented.

Fitting by `method="mle"` to long series can be very slow.

`arima.sim` for simulation of AR processes.

**Examples**

```
ar(lh)
ar(lh, method = "burg")
ar(lh, method = "ols")
ar(lh, FALSE, 4) # fit ar(4)

(sunspot.ar <- ar(sunspot.year))
predict(sunspot.ar, n.ahead = 25)
try the other methods too

ar(ts.union(BJsales, BJsales.lead))
Burg is quite different here, as is OLS (see ar.ols)
ar(ts.union(BJsales, BJsales.lead), method = "burg")
```

**Description**

Fit an autoregressive time series model to the data by ordinary least squares, by default selecting the complexity by AIC.

## Usage

```
ar.ols(x, aic = TRUE, order.max = NULL, na.action = na.fail,
 demean = TRUE, intercept = demean, series, ...)
```

## Arguments

|           |                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | A univariate or multivariate time series.                                                                                                                              |
| aic       | Logical flag. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order order.max is fitted. |
| order.max | Maximum order (or order) of model to fit. Defaults to $10 \log_{10}(N)$ where $N$ is the number of observations.                                                       |
| na.action | function to be called to handle missing values.                                                                                                                        |
| demean    | should the AR model be for x minus its mean?                                                                                                                           |
| intercept | should a separate intercept term be fitted?                                                                                                                            |
| series    | names for the series. Defaults to deparse(substitute(x)).                                                                                                              |
| ...       | further arguments to be passed to or from methods.                                                                                                                     |

## Details

ar.ols fits the general AR model to a possibly non-stationary and/or multivariate system of series x. The resulting unconstrained least squares estimates are consistent, even if some of the series are non-stationary and/or co-integrated. For definiteness, note that the AR coefficients have the sign in

$$x_t - \mu = a_0 + a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t$$

where  $a_0$  is zero unless intercept is true, and  $\mu$  is the sample mean if demean is true, zero otherwise.

Order selection is done by AIC if aic is true. This is problematic, as ar.ols does not perform true maximum likelihood estimation. The AIC is computed as if the variance estimate (computed from the variance matrix of the residuals) were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values.

Some care is needed if intercept is true and demean is false. Only use this if the series are roughly centred on zero. Otherwise the computations may be inaccurate or fail entirely.

## Value

A list of class "ar" with the following elements:

|             |                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| order       | The order of the fitted model. This is chosen by minimizing the AIC if aic = TRUE, otherwise it is order.max.                             |
| ar          | Estimated autoregression coefficients for the fitted model.                                                                               |
| var.pred    | The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model. |
| x.mean      | The estimated mean (or zero if demean is false) of the series used in fitting and for use in prediction.                                  |
| x.intercept | The intercept in the model for x - x.mean, or zero if intercept is false.                                                                 |

|             |                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| aic         | The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of -Inf.                                         |
| n.used      | The number of observations in the time series.                                                                                                              |
| order.max   | The value of the order.max argument.                                                                                                                        |
| partialacf  | NULL. For compatibility with ar.                                                                                                                            |
| resid       | residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If x is a time series, so is resid. |
| method      | The character string "Unconstrained LS".                                                                                                                    |
| series      | The name(s) of the time series.                                                                                                                             |
| frequency   | The frequency of the time series.                                                                                                                           |
| call        | The matched call.                                                                                                                                           |
| asy.se.coef | The asymptotic-theory standard errors of the coefficient estimates.                                                                                         |

**Examples**

```
ar(lh, method = "burg")
ar.ols(lh)
ar.ols(lh, FALSE, 4) # fit ar(4)

ar.ols(ts.union(BJsales, BJsales.lead))

x <- diff(log(EuStockMarkets))
ar.ols(x, order.max = 6, demean = FALSE, intercept = TRUE)
```

**Description**

Fit an ARIMA model to a univariate time series.

## Usage

```
arima(x, order = c(0, 0, 0),
 seasonal = list(order = c(0, 0, 0), period = NA),
 xreg = NULL, include.mean = TRUE,
 transform.pars = TRUE,
 fixed = NULL, init = NULL,
 method = c("CSS-ML", "ML", "CSS"),
 n.cond, optim.method = "BFGS",
 optim.control = list(), kappa = 1e6)
```

## Arguments

|                             |                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>              | a univariate time series                                                                                                                                                                                                                                                                                                                                                        |
| <code>order</code>          | A specification of the non-seasonal part of the ARIMA model: the three components ( $p, d, q$ ) are the AR order, the degree of differencing, and the MA order.                                                                                                                                                                                                                 |
| <code>seasonal</code>       | A specification of the seasonal part of the ARIMA model, plus the period (which defaults to <code>frequency(x)</code> ). This should be a list with components <code>order</code> and <code>period</code> , but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the <code>order</code> .                     |
| <code>xreg</code>           | Optionally, a vector or matrix of external regressors, which must have the same number of rows as <code>x</code> .                                                                                                                                                                                                                                                              |
| <code>include.mean</code>   | Should the ARMA model include a mean/intercept term? The default is <code>TRUE</code> for undifferenced series, and it is ignored for ARIMA models with differencing.                                                                                                                                                                                                           |
| <code>transform.pars</code> | Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for <code>method = "CSS"</code> .                                                                                                                                                                                                                        |
| <code>fixed</code>          | optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in <code>fixed</code> will be varied. <code>transform.pars = TRUE</code> will be overridden (with a warning) if any AR parameters are fixed. It may be wise to set <code>transform.pars = FALSE</code> when fixing MA parameters, especially near non-invertibility. |
| <code>init</code>           | optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in <code>fixed</code> will be ignored.                                                                                                                                                                            |
| <code>method</code>         | Fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood.                                                                                                                                                                 |
| <code>n.cond</code>         | Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.                                                                                                                                                                                                                |
| <code>optim.method</code>   | The value passed as the <code>method</code> argument to <code>optim</code> .                                                                                                                                                                                                                                                                                                    |
| <code>optim.control</code>  | List of control parameters for <code>optim</code> .                                                                                                                                                                                                                                                                                                                             |
| <code>kappa</code>          | the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. Do not reduce this.                                                                                                                                                                                                                                            |

## Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition used here has

$$X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \cdots + b_q e_{t-q}$$

and so the MA coefficients differ in sign from those of S-PLUS. Further, if `include.mean` is true (the default for an ARMA model), this formula applies to  $X - m$  rather than  $X$ . For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model. If an `xreg` term is included, a linear regression (with a constant term if `include.mean` is true and there is no differencing) is fitted with an ARMA model for the error term.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide.

Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

## Value

A list of class "Arima" with components:

|                        |                                                                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>coef</code>      | a vector of AR, MA and regression coefficients, which can be extracted by the <code>coef</code> method.                                                                                          |
| <code>sigma2</code>    | the MLE of the innovations variance.                                                                                                                                                             |
| <code>var.coef</code>  | the estimated variance matrix of the coefficients <code>coef</code> , which can be extracted by the <code>vcov</code> method.                                                                    |
| <code>loglik</code>    | the maximized log-likelihood (of the differenced data), or the approximation to it used.                                                                                                         |
| <code>arma</code>      | A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences. |
| <code>aic</code>       | the AIC value corresponding to the log-likelihood. Only valid for <code>method = "ML"</code> fits.                                                                                               |
| <code>residuals</code> | the fitted innovations.                                                                                                                                                                          |
| <code>call</code>      | the matched call.                                                                                                                                                                                |
| <code>series</code>    | the name of the series <code>x</code> .                                                                                                                                                          |
| <code>code</code>      | the convergence value returned by <code>optim</code> .                                                                                                                                           |
| <code>n.cond</code>    | the number of initial observations not used in the fitting.                                                                                                                                      |
| <code>model</code>     | A list representing the Kalman Filter used in the fitting. See <code>KalmanLike</code> .                                                                                                         |

## Fitting methods

The exact likelihood is computed via a state-space representation of the ARIMA process, and the innovations and their variance found by a Kalman filter. The initialization of the differenced ARMA process uses stationarity and is based on Gardner *et al.* (1980). For a differenced process the non-stationary components are given a diffuse prior (controlled by `kappa`). Observations which are still controlled by the diffuse prior (determined by having a Kalman gain of at least 1e4) are excluded from the likelihood calculations. (This gives comparable results to `arima0` in the absence of missing values, when the observations excluded are precisely those dropped by the differencing.)

Missing values are allowed, and are handled exactly in method "ML".

If `transform.pars` is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p)

model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are not constrained to be invertible during optimization, but they will be converted to invertible form after optimization if `transform.pars` is true.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation `n.cond` on, (where `n.cond` is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument `n.cond` can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

### Note

The results are likely to be different from S-PLUS’s `arima.mle`, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by `arima.mle` reverses the signs of the MA coefficients.

`arima` is very similar to `arima0` for ARMA models or for differenced models without missing values, but handles differenced models with missing values exactly. It is somewhat slower than `arima0`, particularly for seasonally differenced models.

**arima.sim***Simulate from an ARIMA Model***Description**

Simulate from an ARIMA model.

**Usage**

```
arima.sim(model, n, rand.gen = rnorm, innov = rand.gen(n, ...),
 n.start = NA, start.innov = rand.gen(n.start, ...),
 ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>       | A list with component <code>ar</code> and/or <code>ma</code> giving the AR and MA coefficients respectively. Optionally a component <code>order</code> can be used. An empty list gives an ARIMA(0, 0, 0) model, that is white noise. |
| <code>n</code>           | length of output series, before un-differencing. A strictly positive integer.                                                                                                                                                         |
| <code>rand.gen</code>    | optional: a function to generate the innovations.                                                                                                                                                                                     |
| <code>innov</code>       | an optional times series of innovations. If not provided, <code>rand.gen</code> is used.                                                                                                                                              |
| <code>n.start</code>     | length of ‘burn-in’ period. If NA, the default, a reasonable value is computed.                                                                                                                                                       |
| <code>start.innov</code> | an optional times series of innovations to be used for the burn-in period. If supplied there must be at least <code>n.start</code> values (and <code>n.start</code> is by default computed inside the function).                      |
| <code>...</code>         | additional arguments for <code>rand.gen</code> . Most usefully, the standard deviation of the innovations generated by <code>rnorm</code> can be specified by <code>sd</code> .                                                       |

**Details**

See [arima](#) for the precise definition of an ARIMA model.

The ARMA model is checked for stationarity.

ARIMA models are specified via the `order` component of `model`, in the same way as for [arima](#). Other aspects of the `order` component are ignored, but inconsistent specifications of the MA and AR orders are detected. The un-differencing assumes previous values of zero, and to remind the user of this, those values are returned.

Random inputs for the ‘burn-in’ period are generated by calling `rand.gen`.

**Value**

A time-series object of class "ts".

**See Also**

[arima](#)

**Examples**

```
require(graphics)

arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
 sd = sqrt(0.1796))
mildly long-tailed
arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
 rand.gen = function(n, ...) sqrt(0.1796) * rt(n, df = 5))

An ARIMA simulation
ts.sim <- arima.sim(list(order = c(1,1,0), ar = 0.7), n = 200)
ts.plot(ts.sim)
```

**Description**

Fit an ARIMA model to a univariate time series, and forecast from the fitted model.

**Usage**

```
arima0(x, order = c(0, 0, 0),
 seasonal = list(order = c(0, 0, 0), period = NA),
 xreg = NULL, include.mean = TRUE, delta = 0.01,
 transform.pars = TRUE, fixed = NULL, init = NULL,
 method = c("ML", "CSS"), n.cond, optim.control = list())

S3 method for class arima0
predict(object, n.ahead = 1, newxreg, se.fit = TRUE, ...)
```

**Arguments**

- |                       |                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a univariate time series                                                                                                                                                                                                                                                                                                                      |
| <code>order</code>    | A specification of the non-seasonal part of the ARIMA model: the three components $(p, d, q)$ are the AR order, the degree of differencing, and the MA order.                                                                                                                                                                                 |
| <code>seasonal</code> | A specification of the seasonal part of the ARIMA model, plus the period (which defaults to <code>frequency(x)</code> ). This should be a list with components <code>order</code> and <code>period</code> , but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order. |
| <code>xreg</code>     | Optionally, a vector or matrix of external regressors, which must have the same number of rows as <code>x</code> .                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                           |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>include.mean</code>   | Should the ARIMA model include a mean term? The default is TRUE for undifferenced series, FALSE for differenced ones (where a mean would not affect the fit nor predictions).                                                                             |
| <code>delta</code>          | A value to indicate at which point ‘fast recursions’ should be used. See the ‘Details’ section.                                                                                                                                                           |
| <code>transform.pars</code> | Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for <code>method = "CSS"</code> .                                                                                                  |
| <code>fixed</code>          | optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in <code>fixed</code> will be varied. <code>transform.pars = TRUE</code> will be overridden (with a warning) if any ARMA parameters are fixed. |
| <code>init</code>           | optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in <code>fixed</code> will be ignored.                                                      |
| <code>method</code>         | Fitting method: maximum likelihood or minimize conditional sum-of-squares.                                                                                                                                                                                |
| <code>n.cond</code>         | Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.                                                                                          |
| <code>optim.control</code>  | List of control parameters for <code>optim</code> .                                                                                                                                                                                                       |
| <code>object</code>         | The result of an <code>arima0</code> fit.                                                                                                                                                                                                                 |
| <code>newxreg</code>        | New values of <code>xreg</code> to be used for prediction. Must have at least <code>n.ahead</code> rows.                                                                                                                                                  |
| <code>n.ahead</code>        | The number of steps ahead for which prediction is required.                                                                                                                                                                                               |
| <code>se.fit</code>         | Logical: should standard errors of prediction be returned?                                                                                                                                                                                                |
| ...                         | arguments passed to or from other methods.                                                                                                                                                                                                                |

## Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition here has

$$X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \cdots + b_q e_{t-q}$$

and so the MA coefficients differ in sign from those of S-PLUS. Further, if `include.mean` is true, this formula applies to  $X - m$  rather than  $X$ . For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide, especially for fits close to the boundary of invertibility.

Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Finite-history prediction is used. This is only statistically efficient if the MA part of the fit is invertible, so `predict.arima0` will give a warning for non-invertible MA models.

## Value

For `arima0`, a list of class “`arima0`” with components:

|                       |                                                                       |
|-----------------------|-----------------------------------------------------------------------|
| <code>coef</code>     | a vector of AR, MA and regression coefficients,                       |
| <code>sigma2</code>   | the MLE of the innovations variance.                                  |
| <code>var.coef</code> | the estimated variance matrix of the coefficients <code>coef</code> . |

|             |                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| loglik      | the maximized log-likelihood (of the differenced data), or the approximation to it used.                                                                                                         |
| arma        | A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences. |
| aic         | the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.                                                                                                            |
| residuals   | the fitted innovations.                                                                                                                                                                          |
| call        | the matched call.                                                                                                                                                                                |
| series      | the name of the series x.                                                                                                                                                                        |
| convergence | the value returned by <a href="#">optim</a> .                                                                                                                                                    |
| n.cond      | the number of initial observations not used in the fitting.                                                                                                                                      |

For predict.arima0, a time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.

### Fitting methods

The exact likelihood is computed via a state-space representation of the ARMA process, and the innovations and their variance found by a Kalman filter based on Gardner *et al.* (1980). This has the option to switch to ‘fast recursions’ (assume an effectively infinite past) if the innovations variance is close enough to its asymptotic bound. The argument delta sets the tolerance: at its default value the approximation is normally negligible and the speed-up considerable. Exact computations can be ensured by setting delta to a negative value.

If transform.pars is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are also constrained to be invertible during optimization by the same transformation if transform.pars is true. Note that the MLE for MA terms does sometimes occur for MA polynomials with unit roots: such models can be fitted by using transform.pars = FALSE and specifying a good set of initial values (often obtainable from a fit with transform.pars = TRUE).

Missing values are allowed, but any missing values will force delta to be ignored and full recursions used. Note that missing values will be propagated by differencing, so the procedure used in this function is not fully efficient in that case.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation n.cond on, (where n.cond is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument n.cond can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

### Note

This is a preliminary version, and will be replaced by [arima](#).

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients.

The results are likely to be different from S-PLUS's `arima.mle`, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by `arima.mle` reverses the signs of the MA coefficients.

tsdiag(fit3)
End(Not run)
```

## Description

Compute the theoretical autocorrelation function or partial autocorrelation function for an ARMA process.

## Usage

```
ARMAacf(ar = numeric(), ma = numeric(), lag.max = r, pacf = FALSE)
```

## Arguments

|         |                                                                                                                           |
|---------|---------------------------------------------------------------------------------------------------------------------------|
| ar      | numeric vector of AR coefficients                                                                                         |
| ma      | numeric vector of MA coefficients                                                                                         |
| lag.max | integer. Maximum lag required. Defaults to $\max(p, q+1)$ , where $p, q$ are the numbers of AR and MA terms respectively. |
| pacf    | logical. Should the partial autocorrelations be returned?                                                                 |

## Details

The methods used follow Brockwell & Davis (1991, section 3.3). Their equations (3.3.8) are solved for the autocovariances at lags  $0, \dots, \max(p, q + 1)$ , and the remaining autocorrelations are given by a recursive filter.

## Value

A vector of (partial) autocorrelations, named by the lags.

## References

Brockwell, P. J. and Davis, R. A. (1991) *Time Series: Theory and Methods*, Second Edition. Springer.

## See Also

## Examples

```
ARMAacf(c(1.0, -0.25), 1.0, lag.max = 10)

Example from Brockwell & Davis (1991, pp.92-4)
answer 2^{-n} * (32/3 + 8 * n) / (32/3)
n <- 1:10; 2^{-(n)} * (32/3 + 8 * n) / (32/3)
ARMAacf(c(1.0, -0.25), 1.0, lag.max = 10, pacf = TRUE)
zapsmall(ARMAacf(c(1.0, -0.25), lag.max = 10, pacf = TRUE))

Cov-Matrix of length-7 sub-sample of AR(1) example:
toeplitz(ARMAacf(0.8, lag.max = 7))
```

---

**ARMAtoMA***Convert ARMA Process to Infinite MA Process*

---

**Description**

Convert ARMA process to infinite MA process.

**Usage**

```
ARMAtoMA(ar = numeric(), ma = numeric(), lag.max)
```

**Arguments**

|         |                                       |
|---------|---------------------------------------|
| ar      | numeric vector of AR coefficients     |
| ma      | numeric vector of MA coefficients     |
| lag.max | Largest MA(Inf) coefficient required. |

**Value**

A vector of coefficients.

**References**

Brockwell, P. J. and Davis, R. A. (1991) *Time Series: Theory and Methods*, Second Edition. Springer.

**See Also**

[arima](#), [ARMAacf](#).

**Examples**

```
ARMAtoMA(c(1.0, -0.25), 1.0, 10)
Example from Brockwell & Davis (1991, p.92)
answer (1 + 3*n)*2^{(-n)}
n <- 1:10; (1 + 3*n)*2^{(-n)}
```

---

**as.hclust***Convert Objects to Class hclust*

---

**Description**

Converts objects from other hierarchical clustering functions to class "hclust".

**Usage**

```
as.hclust(x, ...)
```

**Arguments**

- x Hierarchical clustering object
- ... further arguments passed to or from other methods.

**Details**

Currently there is only support for converting objects of class "twins" as produced by the functions `diana` and `agnes` from the package **cluster**. The default method throws an error unless passed an "hclust" object.

**Value**

An object of class "hclust".

**See Also**

[hclust](#), and from package **cluster**, `diana` and `agnes`

**Examples**

```

x <- matrix(rnorm(30), ncol = 3)
hc <- hclust(dist(x), method = "complete")

if(require("cluster", quietly = TRUE)) {# is a recommended package
 ag <- agnes(x, method = "complete")
 hcag <- as.hclust(ag)
 ## The dendrograms order slightly differently:
 op <- par(mfrow = c(1,2))
 plot(hc) ; mtext("hclust", side = 1)
 plot(hcag); mtext("agnes", side = 1)
 detach("package:cluster")
}

```

**Description**

Names, expressions, numeric values, and character strings are converted to one-sided formulae. If object is a formula, it must be one-sided, in which case it is returned unaltered.

**Usage**

```
asOneSidedFormula(object)
```

**Arguments**

- |        |                                                                             |
|--------|-----------------------------------------------------------------------------|
| object | a one-sided formula, an expression, a numeric value, or a character string. |
|--------|-----------------------------------------------------------------------------|

**Value**

a one-sided formula representing object

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

[formula](#)

**Examples**

```
asOneSidedFormula("age")
asOneSidedFormula(~ age)
```

---

ave

*Group Averages Over Level Combinations of Factors*

---

**Description**

Subsets of  $x[]$  are averaged, where each subset consist of those observations with the same factor levels.

**Usage**

```
ave(x, ..., FUN = mean)
```

**Arguments**

|     |                                                                     |
|-----|---------------------------------------------------------------------|
| x   | A numeric.                                                          |
| ... | Grouping variables, typically factors, all of the same length as x. |
| FUN | Function to apply for each factor level combination.                |

**Value**

A numeric vector, say  $y$  of length  $\text{length}(x)$ . If  $\dots$  is  $g_1, g_2$ , e.g.,  $y[i]$  is equal to  $\text{FUN}(x[j])$ , for all  $j$  with  $g_1[j] == g_1[i]$  and  $g_2[j] == g_2[i]$ .

**See Also**

[mean](#), [median](#).

**Examples**

```
require(graphics)

ave(1:3) # no grouping -> grand mean

attach(warpbreaks)
ave(breaks, wool)
ave(breaks, tension)
ave(breaks, tension, FUN = function(x) mean(x, trim = 0.1))
plot(breaks, main =
 "ave(Warpbreaks) for wool x tension combinations")
lines(ave(breaks, wool, tension), type = "s", col = "blue")
```

```
lines(ave(breaks, wool, tension, FUN = median), type = "s", col = "green")
legend(40, 70, c("mean", "median"), lty = 1,
 col = c("blue", "green"), bg = "gray90")
detach()
```

**bandwidth***Bandwidth Selectors for Kernel Density Estimation***Description**

Bandwidth selectors for Gaussian kernels in [density](#).

**Usage**

```
bw.nrd0(x)

bw.nrd(x)

bw.ucv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
 tol = 0.1 * lower)

bw.bcv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
 tol = 0.1 * lower)

bw.SJ(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
 method = c("ste", "dpi"), tol = 0.1 * lower)
```

**Arguments**

|                                         |                                                                                                                                                                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                          | numeric vector.                                                                                                                                                                                                                                                                              |
| <code>nb</code>                         | number of bins to use.                                                                                                                                                                                                                                                                       |
| <code>lower</code> , <code>upper</code> | range over which to minimize. The default is almost always satisfactory. <code>hmax</code> is calculated internally from a normal reference bandwidth.                                                                                                                                       |
| <code>method</code>                     | either <code>"ste"</code> ("solve-the-equation") or <code>"dpi"</code> ("direct plug-in").                                                                                                                                                                                                   |
| <code>tol</code>                        | for method <code>"ste"</code> , the convergence tolerance for <a href="#">uniroot</a> . The default leads to bandwidth estimates with only slightly more than one digit accuracy, which is sufficient for practical density estimation, but possibly not for theoretical simulation studies. |

**Details**

`bw.nrd0` implements a rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator. It defaults to 0.9 times the minimum of the standard deviation and the interquartile range divided by 1.34 times the sample size to the negative one-fifth power (= Silverman's 'rule of thumb', Silverman (1986, page 48, eqn (3.31)) *unless* the quartiles coincide when a positive result will be guaranteed.

`bw.nrd` is the more common variation given by Scott (1992), using factor 1.06.

`bw.ucv` and `bw.bcv` implement unbiased and biased cross-validation respectively.

`bw.SJ` implements the methods of Sheather & Jones (1991) to select the bandwidth using pilot estimation of derivatives.

The algorithm for method "ste" solves an equation (via [uniroot](#)) and because of that, enlarges the interval `c(lower, upper)` when the boundaries were not user-specified and do not bracket the root.

### Value

A bandwidth on a scale suitable for the `bw` argument of `density`.

lines(density(precip, bw = "SJ-dpi"), col = 6)
legend(55, 0.035,
 legend = c("nrd0", "nrd", "ucv", "bcv", "SJ-ste", "SJ-dpi"),
 col = 1:6, lty = 1)
```

`bartlett.test`

*Bartlett Test of Homogeneity of Variances*

### Description

Performs Bartlett's test of the null that the variances in each of the groups (samples) are the same.

### Usage

```
bartlett.test(x, ...)

Default S3 method:
bartlett.test(x, g, ...)

S3 method for class formula
bartlett.test(formula, data, subset, na.action, ...)
```

### Arguments

|                        |                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a numeric vector of data values, or a list of numeric data vectors representing the respective samples, or fitted linear model objects (inheriting from class "lm").                                                       |
| <code>g</code>         | a vector or factor object giving the group for the corresponding elements of <code>x</code> . Ignored if <code>x</code> is a list.                                                                                         |
| <code>formula</code>   | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.                                                                                   |
| <code>data</code>      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| <code>...</code>       | further arguments to be passed to or from methods.                                                                                                                                                                         |

### Details

If `x` is a list, its elements are taken as the samples or fitted linear models to be compared for homogeneity of variances. In this case, the elements must either all be numeric data vectors or fitted linear model objects, `g` is ignored, and one can simply use `bartlett.test(x)` to perform the test. If the samples are not yet contained in a list, use `bartlett.test(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

### Value

A list of class "htest" containing the following components:

|                        |                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------|
| <code>statistic</code> | Bartlett's K-squared test statistic.                                                      |
| <code>parameter</code> | the degrees of freedom of the approximate chi-squared distribution of the test statistic. |
| <code>p.value</code>   | the p-value of the test.                                                                  |
| <code>method</code>    | the character string "Bartlett test of homogeneity of variances".                         |
| <code>data.name</code> | a character string giving the names of the data.                                          |

```

Beta

*The Beta Distribution*

## Description

Density, distribution function, quantile function and random generation for the Beta distribution with parameters `shape1` and `shape2` (and optional non-centrality parameter `ncp`).

## Usage

```
dbeta(x, shape1, shape2, ncp = 0, log = FALSE)
pbeta(q, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qbeta(p, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rbeta(n, shape1, shape2, ncp = 0)
```

## Arguments

|                             |                                                                                                           |
|-----------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>           | vector of quantiles.                                                                                      |
| <code>p</code>              | vector of probabilities.                                                                                  |
| <code>n</code>              | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>shape1, shape2</code> | positive parameters of the Beta distribution.                                                             |
| <code>ncp</code>            | non-centrality parameter.                                                                                 |
| <code>log, log.p</code>     | logical; if TRUE, probabilities p are given as log(p).                                                    |
| <code>lower.tail</code>     | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

## Details

The Beta distribution with parameters `shape1 = a` and `shape2 = b` has density

$$f(x) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} x^{a-1} (1-x)^{b-1}$$

for  $a > 0, b > 0$  and  $0 \leq x \leq 1$  where the boundary values at  $x = 0$  or  $x = 1$  are defined as by continuity (as limits).

The mean is  $a/(a+b)$  and the variance is  $ab/((a+b)^2(a+b+1))$ .

`pbeta` is closely related to the incomplete beta function. As defined by Abramowitz and Stegun 6.6.1

$$B_x(a, b) = \int_0^x t^{a-1} (1-t)^{b-1} dt,$$

and 6.6.2  $I_x(a, b) = B_x(a, b)/B(a, b)$  where  $B(a, b) = B_1(a, b)$  is the Beta function ([beta](#)).

$I_x(a, b)$  is `pbeta(x, a, b)`.

The noncentral Beta distribution (with `ncp = λ`) is defined (Johnson et al, 1995, pp. 502) as the distribution of  $X/(X + Y)$  where  $X \sim \chi_{2a}^2(\lambda)$  and  $Y \sim \chi_{2b}^2$ .

**Value**

`dbeta` gives the density, `pbeta` the distribution function, `qbeta` the quantile function, and `rbeta` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rbeta`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Note**

Supplying `ncp = 0` uses the algorithm for the non-central distribution, which is not the same algorithm used if `ncp` is omitted. This is to give consistent behaviour in extreme cases with values of `ncp` very near zero.

**Source**

The central `dbeta` is based on a binomial probability, using code contributed by Catherine Loader (see `dbinom`) if either shape parameter is larger than one, otherwise directly from the definition. The non-central case is based on the derivation as a Poisson mixture of betas (Johnson *et al*, 1995, pp. 502–3).

The central `pbeta` uses a C translation (and enhancement for `log_p = TRUE`) of

Didonato, A. and Morris, A., Jr, (1992) Algorithm 708: Significant digit computation of the incomplete beta function ratios, *ACM Transactions on Mathematical Software*, **18**, 360–373. (See also Brown, B. and Lawrence Levy, L. (1994) Certification of algorithm 708: Significant digit computation of the incomplete beta, *ACM Transactions on Mathematical Software*, **20**, 393–397.)

The non-central `pbeta` uses a C translation of

Lenth, R. V. (1987) Algorithm AS226: Computing noncentral beta probabilities. *Appl. Statist.*, **36**, 241–244, incorporating

Frick, H. (1990)'s AS R84, *Appl. Statist.*, **39**, 311–2, and  
Lam, M.L. (1995)'s AS R95, *Appl. Statist.*, **44**, 551–2.

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

The central case of `qbeta` is based on a C translation of

Cran, G. W., K. J. Martin and G. E. Thomas (1977). Remark AS R19 and Algorithm AS 109, *Applied Statistics*, **26**, 111–114, and subsequent remarks (AS83 and correction).

The central case of `rbeta` is based on a C translation of

R. C. H. Cheng (1978). Generating beta variates with nonintegral shape parameters. *Communications of the ACM*, **21**, 317–322.

## Examples

```
x <- seq(0, 1, length = 21)
dbeta(x, 1, 1)
pbeta(x, 1, 1)
```

---

binom.test

*Exact Binomial Test*

---

## Description

Performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli experiment.

## Usage

```
binom.test(x, n, p = 0.5,
 alternative = c("two.sided", "less", "greater"),
 conf.level = 0.95)
```

## Arguments

|                          |                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | number of successes, or a vector of length 2 giving the numbers of successes and failures, respectively.                           |
| <code>n</code>           | number of trials; ignored if <code>x</code> has length 2.                                                                          |
| <code>p</code>           | hypothesized probability of success.                                                                                               |
| <code>alternative</code> | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. |
| <code>conf.level</code>  | confidence level for the returned confidence interval.                                                                             |

## Details

Confidence intervals are obtained by a procedure first given in Clopper and Pearson (1934). This guarantees that the confidence level is at least `conf.level`, but in general does not give the shortest-length confidence intervals.

## Value

A list with class "htest" containing the following components:

|                        |                                                       |
|------------------------|-------------------------------------------------------|
| <code>statistic</code> | the number of successes.                              |
| <code>parameter</code> | the number of trials.                                 |
| <code>p.value</code>   | the p-value of the test.                              |
| <code>conf.int</code>  | a confidence interval for the probability of success. |
| <code>estimate</code>  | the estimated probability of success.                 |

|             |                                                           |
|-------------|-----------------------------------------------------------|
| null.value  | the probability of success under the null, p.             |
| alternative | a character string describing the alternative hypothesis. |
| method      | the character string "Exact binomial test".               |
| data.name   | a character string giving the names of the data.          |

## See Also

[prop.test](#) for a general (approximate) test for equal or given proportions.

## Examples

```
Conover (1971), p. 97f.
Under (the assumption of) simple Mendelian inheritance, a cross
between plants of two particular genotypes produces progeny 1/4 of
which are "dwarf" and 3/4 of which are "giant", respectively.
In an experiment to determine if this assumption is reasonable, a
cross results in progeny having 243 dwarf and 682 giant plants.
If "giant" is taken as success, the null hypothesis is that p =
3/4 and the alternative that p != 3/4.
binom.test(c(682, 243), p = 3/4)
binom.test(682, 682 + 243, p = 3/4) # The same.
=> Data are in agreement with the null hypothesis.
```

## Description

Density, distribution function, quantile function and random generation for the binomial distribution with parameters size and prob.

## Usage

```
dbinom(x, size, prob, log = FALSE)
pbinom(q, size, prob, lower.tail = TRUE, log.p = FALSE)
qbinom(p, size, prob, lower.tail = TRUE, log.p = FALSE)
rbinom(n, size, prob)
```

## Arguments

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                      |
| <code>p</code>          | vector of probabilities.                                                                                  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>size</code>       | number of trials (zero or more).                                                                          |
| <code>prob</code>       | probability of success on each trial.                                                                     |
| <code>log, log.p</code> | logical; if TRUE, probabilities p are given as log(p).                                                    |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

## Details

The binomial distribution with `size = n` and `prob = p` has density

$$p(x) = \binom{n}{x} p^x (1-p)^{n-x}$$

for  $x = 0, \dots, n$ . Note that binomial coefficients can be computed by `choose` in R.

If an element of `x` is not integer, the result of `dbinom` is zero, with a warning.  $p(x)$  is computed using Loader's algorithm, see the reference below.

The quantile is defined as the smallest value  $x$  such that  $F(x) \geq p$ , where  $F$  is the distribution function.

## Value

`dbinom` gives the density, `pbinom` gives the distribution function, `qbinom` gives the quantile function and `rbinom` generates random deviates.

If `size` is not an integer, NaN is returned.

The length of the result is determined by `n` for `rbinom`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

## Source

For `dbinom` a saddle-point expansion is used: see

Catherine Loader (2000). *Fast and Accurate Computation of Binomial Probabilities*; available from <http://www.herne.net/stat/software/dbinom.html>.

`pbinom` uses `pbeta`.

`qbinom` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

`rbinom` (for `size < .Machine$integer.max`) is based on

Kachitvichyanukul, V. and Schmeiser, B. W. (1988) Binomial random variate generation. *Communications of the ACM*, **31**, 216–222.

For larger values it uses inversion.

**See Also**

[Distributions](#) for other standard distributions, including [dnbinom](#) for the negative binomial, and [dpois](#) for the Poisson distribution.

**Examples**

```
require(graphics)
Compute P(45 < X < 55) for X Binomial(100,0.5)
sum(dbinom(46:54, 100, 0.5))

Using "log = TRUE" for an extended range :
n <- 2000
k <- seq(0, n, by = 20)
plot (k, dbinom(k, n, pi/10, log = TRUE), type = "l", ylab = "log density",
 main = "dbinom(*, log=TRUE) is better than log(dbinom(*))")
lines(k, log(dbinom(k, n, pi/10)), col = "red", lwd = 2)
extreme points are omitted since dbinom gives 0.
mtext("dbinom(k, log=TRUE)", adj = 0)
mtext("extended range", adj = 0, line = -1, font = 4)
mtext("log(dbinom(k))", col = "red", adj = 1)
```

**biplot***Biplot of Multivariate Data***Description**

Plot a biplot on the current graphics device.

**Usage**

```
biplot(x, ...)

Default S3 method:
biplot(x, y, var.axes = TRUE, col, cex = rep(par("cex"), 2),
 xlabs = NULL, ylabs = NULL, expand = 1,
 xlim = NULL, ylim = NULL, arrow.len = 0.1,
 main = NULL, sub = NULL, xlab = NULL, ylab = NULL, ...)
```

**Arguments**

- x The biplot, a fitted object. For `biplot.default`, the first set of points (a two-column matrix), usually associated with observations.
- y The second set of points (a two-column matrix), usually associated with variables.
- var.axes If TRUE the second set of points have arrows representing them as (unscaled) axes.
- col A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the [palette](#): if there it and the next colour are used, otherwise the first two colours of the palette are used.

|                            |                                                                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cex                        | The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.                           |
| xlabs                      | A vector of character strings to label the first set of points: the default is to use the row dimname of x, or 1:n if the dimname is NULL.                                         |
| ylabs                      | A vector of character strings to label the second set of points: the default is to use the row dimname of y, or 1:n if the dimname is NULL.                                        |
| expand                     | An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale. |
| arrow.len                  | The length of the arrow heads on the axes plotted in var.axes is true. The arrow head can be suppressed by arrow.len = 0.                                                          |
| xlim, ylim                 | Limits for the x and y axes in the units of the first set of variables.                                                                                                            |
| main, sub, xlab, ylab, ... | graphical parameters.                                                                                                                                                              |

## Details

A biplot is plot which aims to represent both the observations and variables of a matrix of multivariate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by [biplot.princomp](#). The function [biplot.default](#) merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to [biplot](#): the size of xlabs and ylabs is controlled by cex.

## Side Effects

a plot is produced on the current graphics device.

## References

 J.C. Gower and D. J. Hand (1996). *Biplots*. Chapman & Hall.

## See Also

[biplot.princomp](#), also for examples.

## Description

Produces a biplot (in the strict sense) from the output of [princomp](#) or [prcomp](#)

## Usage

```
S3 method for class prcomp
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

S3 method for class princomp
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object of class "princomp".                                                                                                                                                                                                                                                                                                                       |
| <code>choices</code>   | length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.                                                                                                                                                                                                                                                 |
| <code>scale</code>     | The variables are scaled by <code>lambda ^ scale</code> and the observations are scaled by <code>lambda ^ (1-scale)</code> where <code>lambda</code> are the singular values as computed by <code>princomp</code> . Normally $0 \leq scale \leq 1$ , and a warning will be issued if the specified scale is outside this range.                      |
| <code>pc.biplot</code> | If true, use what Gabriel (1971) refers to as a "principal component biplot", with <code>lambda = 1</code> and observations scaled up by <code>sqrt(n)</code> and variables scaled down by <code>sqrt(n)</code> . Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance. |
| <code>...</code>       | optional arguments to be passed to <code>biplot.default</code> .                                                                                                                                                                                                                                                                                     |

## Details

This is a method for the generic function `biplot`. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to `pc.biplot = TRUE`.

## Side Effects

a plot is produced on the current graphics device.

## Examples

```
require(graphics)
biplot(princomp(USArrests))
```

---

|          |                                    |
|----------|------------------------------------|
| birthday | <i>Probability of coincidences</i> |
|----------|------------------------------------|

---

## Description

Computes answers to a generalised *birthday paradox* problem. pbirthday computes the probability of a coincidence and qbirthday computes the smallest number of observations needed to have at least a specified probability of coincidence.

## Usage

```
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

## Arguments

|            |                                                         |
|------------|---------------------------------------------------------|
| classes    | How many distinct categories the people could fall into |
| prob       | The desired probability of coincidence                  |
| n          | The number of people                                    |
| coincident | The number of people to fall in the same category       |

## Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50–50 chance that two or more of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

The formula used is approximate for  $\text{coincident} > 2$ . The approximation is very good for moderate values of  $\text{prob}$  but less good for very small probabilities.

## Value

|           |                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| qbirthday | Minimum number of people needed for a probability of at least $\text{prob}$ that $k$ or more of them have the same one out of $\text{classes}$ equiprobable labels. |
| pbirthday | Probability of the specified coincidence.                                                                                                                           |

## Note

Prior to R 2.14.0 the approximate formula was used even for  $\text{coincident} = 2$ .

## References

Diaconis, P. and Mosteller F. (1989) Methods for studying coincidences. *J. American Statistical Association*, **84**, 853–861.

## Examples

```
require(graphics)

the standard version
qbirthday() # 23
probability of > 2 people with the same birthday
pbirthday(23, coincident = 3)

examples from Diaconis & Mosteller p. 858.
coincidence is that husband, wife, daughter all born on the 16th
qbirthday(classes = 30, coincident = 3) # approximately 18
qbirthday(coincident = 4) # exact value 187
qbirthday(coincident = 10) # exact value 1181

same 4-digit PIN number
qbirthday(classes = 10^4)

0.9 probability of three or more coincident birthdays
qbirthday(coincident = 3, prob = 0.9)

Chance of 4 or more coincident birthdays in 150 people
pbirthday(150, coincident = 4)

100 or more coincident birthdays in 1000 people: very rare
pbirthday(1000, coincident = 100)
```

Box.test

*Box-Pierce and Ljung-Box Tests*

## Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series. These are sometimes known as ‘portmanteau’ tests.

## Usage

```
Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"), fitdf = 0)
```

## Arguments

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <code>x</code>     | a numeric vector or univariate time series.                                               |
| <code>lag</code>   | the statistic will be based on <code>lag</code> autocorrelation coefficients.             |
| <code>type</code>  | test to be performed: partial matching is used.                                           |
| <code>fitdf</code> | number of degrees of freedom to be subtracted if <code>x</code> is a series of residuals. |

## Details

These tests are sometimes applied to the residuals from an ARMA( $p, q$ ) fit, in which case the references suggest a better approximation to the null-hypothesis distribution is obtained by setting `fitdf = p+q`, provided of course that `lag > fitdf`.

**Value**

A list with class "htest" containing the following components:

|                        |                                                                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code> | the value of the test statistic.                                                                                                   |
| <code>parameter</code> | the degrees of freedom of the approximate chi-squared distribution of the test statistic (taking <code>fitdf</code> into account). |
| <code>p.value</code>   | the p-value of the test.                                                                                                           |
| <code>method</code>    | a character string indicating which type of test was performed.                                                                    |
| <code>data.name</code> | a character string giving the name of the data.                                                                                    |

**Note**

Missing values are not handled.

**Examples**

```
x <- rnorm(100)
Box.test(x, lag = 1)
Box.test(x, lag = 1, type = "Ljung")
```

**Description**

Sets the "contrasts" attribute for the factor.

**Usage**

```
C(object, contr, how.many, ...)
```

**Arguments**

|                       |                                                                                                                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | a factor or ordered factor                                                                                                                                                                  |
| <code>contr</code>    | which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like <code>contr.poly</code> or a character string giving the name of the function |
| <code>how.many</code> | the number of contrasts to set, by default one less than <code>nlevels(object)</code> .                                                                                                     |
| <code>...</code>      | additional arguments for the function <code>contr</code> .                                                                                                                                  |

## Details

For compatibility with S, `contr` can be `treatment`, `helmert`, `sum` or `poly` (without quotes) as shorthand for `contr.treatment` and so on.

## Value

The factor object with the "contrasts" attribute set.

## References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical models*. Chapter 2 of *Statistical Models in S* eds J. M. Chambers and T. J. Hastie, Wadsworth & Brooks/Cole.

## See Also

[contrasts](#), [contr.sum](#), etc.

## Examples

```
reset contrasts to defaults
options(contrasts = c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data = warpbreaks)

show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base = 2), data = warpbreaks))

following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
 C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)
```

## Description

Compute the canonical correlations between two data matrices.

## Usage

```
cancor(x, y, xcenter = TRUE, ycenter = TRUE)
```

## Arguments

- x numeric matrix ( $n \times p_1$ ), containing the x coordinates.
- y numeric matrix ( $n \times p_2$ ), containing the y coordinates.

|         |                                                                                                                                                                                                                                                                          |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xcenter | logical or numeric vector of length $p_1$ , describing any centering to be done on the x values before the analysis. If TRUE (default), subtract the column means. If FALSE, do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns. |
| ycenter | analogous to xcenter, but for the y values.                                                                                                                                                                                                                              |

## Details

The canonical correlation analysis seeks linear combinations of the y variables which are well explained by linear combinations of the x variables. The relationship is symmetric as ‘well explained’ is measured by correlations.

## Value

A list containing the following components:

|         |                                             |
|---------|---------------------------------------------|
| cor     | correlations.                               |
| xcoef   | estimated coefficients for the x variables. |
| ycoef   | estimated coefficients for the y variables. |
| xcenter | the values used to adjust the x variables.  |
| ycenter | the values used to adjust the x variables.  |

 case+variable.names     *Case and Variable Names of Fitted Models*

---

## Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.

## Usage

```
case.names(object, ...)
S3 method for class lm
case.names(object, full = FALSE, ...)

variable.names(object, ...)
S3 method for class lm
variable.names(object, full = FALSE, ...)
```

## Arguments

- |        |                                                                         |
|--------|-------------------------------------------------------------------------|
| object | an R object, typically a fitted model.                                  |
| full   | logical; if TRUE, all names (including zero weights, ...) are returned. |
| ...    | further arguments passed to or from other methods.                      |

## Value

A character vector.

## See Also

[lm](#); further, [all.names](#), [all.vars](#) for functions with a similar name but only slightly related purpose.

## Examples

```
x <- 1:20
y <- setNames(x + (x/4 - 2)^3 + rnorm(20, sd = 3),
 paste("0", x, sep = "."))
ww <- rep(1, 20); ww[13] <- 0
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-10)^2), weights = ww,
 cor = TRUE)
variable.names(lmxy)
variable.names(lmxy, full = TRUE) # includes the last
case.names(lmxy)
case.names(lmxy, full = TRUE) # includes the 0-weight case
```

---

Cauchy*The Cauchy Distribution*

---

**Description**

Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter `location` and scale parameter `scale`.

**Usage**

```
dcauchy(x, location = 0, scale = 1, log = FALSE)
pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rcauchy(n, location = 0, scale = 1)
```

**Arguments**

|                              |                                                                                                           |
|------------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>            | vector of quantiles.                                                                                      |
| <code>p</code>               | vector of probabilities.                                                                                  |
| <code>n</code>               | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>location, scale</code> | location and scale parameters.                                                                            |
| <code>log, log.p</code>      | logical; if TRUE, probabilities p are given as log(p).                                                    |
| <code>lower.tail</code>      | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

If `location` or `scale` are not specified, they assume the default values of 0 and 1 respectively.

The Cauchy distribution with location  $l$  and scale  $s$  has density

$$f(x) = \frac{1}{\pi s} \left( 1 + \left( \frac{x-l}{s} \right)^2 \right)^{-1}$$

for all  $x$ .

**Value**

`dcauchy`, `pcauchy`, and `qcauchy` are respectively the density, distribution function and quantile function of the Cauchy distribution. `rcauchy` generates random deviates from the Cauchy.

The length of the result is determined by `n` for `rcauchy`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Source**

`dcauchy`, `pcauchy` and `qcauchy` are all calculated from numerically stable versions of the definitions.

`rcauchy` uses inversion.

`chisq.test`

*Pearson's Chi-squared Test for Count Data*

## Description

`chisq.test` performs chi-squared contingency table tests and goodness-of-fit tests.

## Usage

```
chisq.test(x, y = NULL, correct = TRUE,
 p = rep(1/length(x), length(x)), rescale.p = FALSE,
 simulate.p.value = FALSE, B = 2000)
```

## Arguments

- |                               |                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                | a numeric vector or matrix. <code>x</code> and <code>y</code> can also both be factors.                                                                                                                                                                                                                             |
| <code>y</code>                | a numeric vector; ignored if <code>x</code> is a matrix. If <code>x</code> is a factor, <code>y</code> should be a factor of the same length.                                                                                                                                                                       |
| <code>correct</code>          | a logical indicating whether to apply continuity correction when computing the test statistic for 2 by 2 tables: one half is subtracted from all $ O - E $ differences; however, the correction will not be bigger than the differences themselves. No correction is done if <code>simulate.p.value = TRUE</code> . |
| <code>p</code>                | a vector of probabilities of the same length of <code>x</code> . An error is given if any entry of <code>p</code> is negative.                                                                                                                                                                                      |
| <code>rescale.p</code>        | a logical scalar; if TRUE then <code>p</code> is rescaled (if necessary) to sum to 1. If <code>rescale.p</code> is FALSE, and <code>p</code> does not sum to 1, an error is given.                                                                                                                                  |
| <code>simulate.p.value</code> | a logical indicating whether to compute p-values by Monte Carlo simulation.                                                                                                                                                                                                                                         |
| <code>B</code>                | an integer specifying the number of replicates used in the Monte Carlo test.                                                                                                                                                                                                                                        |

## Details

If  $x$  is a matrix with one row or column, or if  $x$  is a vector and  $y$  is not given, then a *goodness-of-fit test* is performed ( $x$  is treated as a one-dimensional contingency table). The entries of  $x$  must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in  $p$ , or are all equal if  $p$  is not given.

If  $x$  is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of  $x$  must be non-negative integers. Otherwise,  $x$  and  $y$  must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then Pearson's chi-squared test is performed of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

If `simulate.p.value` is `FALSE`, the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if `correct` is `TRUE`, the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with  $B$  replicates.

In the contingency table case simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation assumed for the chi-squared test but rather that for Fisher's exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by  $p$ , each sample being of size  $n = \text{sum}(x)$ . This simulation is done in R and may be slow.

## Value

A list with class "htest" containing the following components:

|                        |                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code> | the value the chi-squared test statistic.                                                                                                                                                                          |
| <code>parameter</code> | the degrees of freedom of the approximate chi-squared distribution of the test statistic, NA if the p-value is computed by Monte Carlo simulation.                                                                 |
| <code>p.value</code>   | the p-value for the test.                                                                                                                                                                                          |
| <code>method</code>    | a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.                                                                                    |
| <code>data.name</code> | a character string giving the name(s) of the data.                                                                                                                                                                 |
| <code>observed</code>  | the observed counts.                                                                                                                                                                                               |
| <code>expected</code>  | the expected counts under the null hypothesis.                                                                                                                                                                     |
| <code>residuals</code> | the Pearson residuals, $(\text{observed} - \text{expected}) / \sqrt{\text{expected}}$ .                                                                                                                            |
| <code>stdres</code>    | standardized residuals, $(\text{observed} - \text{expected}) / \sqrt{V}$ , where $V$ is the residual cell variance (Agresti, 2007, section 2.4.5 for the case where $x$ is a matrix, $n * p * (1 - p)$ otherwise). |

## Source

The code for Monte Carlo simulation is a C translation of the Fortran algorithm of Patefield (1981).

## Examples

```
From Agresti(2007) p.39
M <- as.table(rbind(c(762, 327, 468), c(484, 239, 477)))
dimnames(M) <- list(gender = c("M", "F"),
 party = c("Democrat", "Independent", "Republican"))
(Xsq <- chisq.test(M)) # Prints test summary
Xsq$observed # observed counts (same as M)
Xsq$expected # expected counts under the null
Xsq$residuals # Pearson residuals
Xsq$stdres # standardized residuals

Effect of simulating p-values
x <- matrix(c(12, 5, 7, 7), ncol = 2)
chisq.test(x)$p.value # 0.4233
chisq.test(x, simulate.p.value = TRUE, B = 10000)$p.value
around 0.29!

Testing for population probabilities
Case A. Tabulated data
x <- c(A = 20, B = 15, C = 25)
chisq.test(x)
chisq.test(as.table(x)) # the same
x <- c(89,37,30,28,2)
p <- c(40,20,20,15,5)
try(
 chisq.test(x, p = p) # gives an error
)
chisq.test(x, p = p, rescale.p = TRUE)
works
p <- c(0.40,0.20,0.20,0.19,0.01)
Expected count in category 5
is 1.86 < 5 ==> chi square approx.
chisq.test(x, p = p) # maybe doubtful, but is ok!
chisq.test(x, p = p, simulate.p.value = TRUE)

Case B. Raw data
x <- trunc(5 * runif(100))
chisq.test(table(x)) # NOT chisq.test(x)!
```

### Description

Density, distribution function, quantile function and random generation for the chi-squared ( $\chi^2$ ) distribution with df degrees of freedom and optional non-centrality parameter ncp.

### Usage

```
dchisq(x, df, ncp = 0, log = FALSE)
pchisq(q, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qchisq(p, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rchisq(n, df, ncp = 0)
```

### Arguments

|            |                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------|
| x, q       | vector of quantiles.                                                                                      |
| p          | vector of probabilities.                                                                                  |
| n          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| df         | degrees of freedom (non-negative, but can be non-integer).                                                |
| ncp        | non-centrality parameter (non-negative).                                                                  |
| log, log.p | logical; if TRUE, probabilities p are given as log(p).                                                    |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

### Details

The chi-squared distribution with  $df = n \geq 0$  degrees of freedom has density

$$f_n(x) = \frac{1}{2^{n/2}\Gamma(n/2)} x^{n/2-1} e^{-x/2}$$

for  $x > 0$ . The mean and variance are  $n$  and  $2n$ .

The non-central chi-squared distribution with  $df = n$  degrees of freedom and non-centrality parameter  $ncp = \lambda$  has density

$$f(x) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} f_{n+2r}(x)$$

for  $x \geq 0$ . For integer  $n$ , this is the distribution of the sum of squares of  $n$  normals each with variance one,  $\lambda$  being the sum of squares of the normal means; further,

$E(X) = n + \lambda$ ,  $Var(X) = 2(n + 2 * \lambda)$ , and  $E((X - E(X))^3) = 8(n + 3 * \lambda)$ .

Note that the degrees of freedom  $df = n$ , can be non-integer, and also  $n = 0$  which is relevant for non-centrality  $\lambda > 0$ , see Johnson et al. (1995, chapter 29).

Note that ncp values larger than about 1e5 may give inaccurate results with many warnings for pchisq and qchisq.

### Value

dchisq gives the density, pchisq gives the distribution function, qchisq gives the quantile function, and rchisq generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rchisq, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

### Note

Supplying `ncp = 0` uses the algorithm for the non-central distribution, which is not the same algorithm used if `ncp` is omitted. This is to give consistent behaviour in extreme cases with values of `ncp` very near zero.

The code for non-zero `ncp` is principally intended to be used for moderate values of `ncp`: it will not be highly accurate, especially in the tails, for large values.

### Source

The central cases are computed via the gamma distribution.

The non-central `dchisq` and `rchisq` are computed as a Poisson mixture central of chi-squares (Johnson et al, 1995, p.436).

The non-central `pchisq` is for `ncp < 80` computed from the Poisson mixture of central chi-squares and for larger `ncp` via a C translation of

Ding, C. G. (1992) Algorithm AS275: Computing the non-central chi-squared distribution function. *Appl.Statist.*, **41** 478–482.

which computes the lower tail only (so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant).

The non-central `qchisq` is based on inversion of `pchisq`.

 all.equal(p.0, exp(-lam/2)))

```

**cmdscale***Classical (Metric) Multidimensional Scaling***Description**

Classical multidimensional scaling of a data matrix. Also known as *principal coordinates analysis* (Gower, 1966).

**Usage**

```
cmdscale(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE)
```

**Arguments**

- |              |                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>d</b>     | a distance structure such as that returned by <code>dist</code> or a full symmetric matrix containing the dissimilarities.                                              |
| <b>k</b>     | the maximum dimension of the space which the data are to be represented in; must be in $\{1, 2, \dots, n - 1\}$ .                                                       |
| <b>eig</b>   | indicates whether eigenvalues should be returned.                                                                                                                       |
| <b>add</b>   | logical indicating if an additive constant $c*$ should be computed, and added to the non-diagonal dissimilarities such that the modified dissimilarities are Euclidean. |
| <b>x.ret</b> | indicates whether the doubly centred symmetric distance matrix should be returned.                                                                                      |

## Details

Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities. (It is a major part of what ecologists call ‘ordination’.)

A set of Euclidean distances on  $n$  points can be represented exactly in at most  $n - 1$  dimensions. cmdscale follows the analysis of Mardia (1978), and returns the best-fitting  $k$ -dimensional representation, where  $k$  may be less than the argument  $k$ .

The representation is only determined up to location (cmdscale takes the column means of the configuration to be at the origin), rotations and reflections. The configuration returned is given in principal-component axes, so the reflection chosen may differ between R platforms (see [prcomp](#)).

When `add = TRUE`, a minimal additive constant  $c*$  is computed such that the dissimilarities  $d_{ij} + c*$  are Euclidean and hence can be represented in  $n - 1$  dimensions. Whereas S (Becker *et al.*, 1988) computes this constant using an approximation suggested by Torgerson, R uses the analytical solution of Cailliez (1983), see also Cox and Cox (2001). Note that because of numerical errors the computed eigenvalues need not all be non-negative, and even theoretically the representation could be in fewer than  $n - 1$  dimensions.

## Value

If `eig = FALSE`, `add = FALSE` and `x.ret = FALSE` (default), a matrix with  $k$  columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a list containing the following components.

|                     |                                                                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>points</code> | a matrix with up to $k$ columns whose rows give the coordinates of the points chosen to represent the dissimilarities.                                                                                                                            |
| <code>eig</code>    | the $n$ eigenvalues computed during the scaling process if <code>eig</code> is true. <b>NB:</b> versions of R before 2.12.1 returned only $k$ but were documented to return $n - 1$ .                                                             |
| <code>x</code>      | the doubly centered distance matrix if <code>x.ret</code> is true.                                                                                                                                                                                |
| <code>ac</code>     | the additive constant $c*$ , 0 if <code>add = FALSE</code> .                                                                                                                                                                                      |
| <code>GOF</code>    | a numeric vector of length 2, equal to say $(g_1, g_2)$ , where $g_i = (\sum_{j=1}^k \lambda_j)/(\sum_{j=1}^n T_i(\lambda_j))$ , where $\lambda_j$ are the eigenvalues (sorted in decreasing order), $T_1(v) =  v $ , and $T_2(v) = \max(v, 0)$ . |

### See Also

[dist](#).

[isoMDS](#) and [sammon](#) in package **MASS** provide alternative methods of multidimensional scaling.

### Examples

```
require(graphics)

loc <- cmdscale(eurodist)
x <- loc[, 1]
y <- -loc[, 2] # reflect so North is at the top
note asp = 1, to ensure Euclidean distances are represented correctly
plot(x, y, type = "n", xlab = "", ylab = "", asp = 1, axes = FALSE,
 main = "cmdscale(eurodist)")
text(x, y, rownames(loc), cex = 0.6)
```

coef

*Extract Model Coefficients*

### Description

coef is a generic function which extracts model coefficients from objects returned by modeling functions. [coefficients](#) is an *alias* for it.

### Usage

```
coef(object, ...)
coefficients(object, ...)
```

### Arguments

- |        |                                                                         |
|--------|-------------------------------------------------------------------------|
| object | an object for which the extraction of model coefficients is meaningful. |
| ...    | other arguments.                                                        |

### Details

All object classes which are returned by model fitting functions should provide a coef method or use the default one. (Note that the method is for coef and not coefficients.)

Class "aov" has a coef method that does not report aliased coefficients (see [alias](#)).

### Value

Coefficients extracted from the model object object.

For standard model fitting classes this will be a named numeric vector.

**Examples**

```
x <- 1:5; coef(lm(c(1:3, 7, 6) ~ x))
```

**complete.cases**

*Find Complete Cases*

**Description**

Return a logical vector indicating which cases are complete, i.e., have no missing values.

**Usage**

```
complete.cases(...)
```

**Arguments**

... a sequence of vectors, matrices and data frames.

**Value**

A logical vector specifying which observations/rows have no missing values across the entire sequence.

**See Also**

[is.na](#), [na.omit](#), [na.fail](#).

**Examples**

```
x <- airquality[, -1] # x is a regression design matrix
y <- airquality[, 1] # y is the corresponding response

stopifnot(complete.cases(y) != is.na(y))
ok <- complete.cases(x, y)
sum(!ok) # how many are not "ok" ?
x <- x[ok,]
y <- y[ok]
```

**confint***Confidence Intervals for Model Parameters***Description**

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class "[lm](#)".

**Usage**

```
confint(object, parm, level = 0.95, ...)
```

**Arguments**

|                     |                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a fitted model object.                                                                                                                                                |
| <code>parm</code>   | a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered. |
| <code>level</code>  | the confidence level required.                                                                                                                                        |
| <code>...</code>    | additional argument(s) for methods.                                                                                                                                   |

**Details**

`confint` is a generic function. The default method assumes asymptotic normality, and needs suitable `coef` and `vcov` methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "`lm`" the direct formulae based on  $t$  values are used.

There are stub methods for classes "`glm`" and "`nls`" which invoke those in package **MASS** which are based on profile likelihoods.

**Value**

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as  $(1-\text{level})/2$  and  $1 - (1-\text{level})/2$  in % (by default 2.5% and 97.5%).

**See Also**

[confint.glm](#) and [confint.nls](#) in package **MASS**.

**Examples**

```
fit <- lm(100/mpg ~ disp + hp + wt + am, data = mtcars)
confint(fit)
confint(fit, "wt")

from example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3, 1, 9); treatment <- gl(3, 3)
glm.D93 <- glm(counts ~ outcome + treatment, family = poisson())
confint(glm.D93) # needs MASS to be present on the system
confint.default(glm.D93) # based on asymptotic normality
```

constrOptim

*Linearly Constrained Optimization***Description**

Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.

**Usage**

```
constrOptim(theta, f, grad, ui, ci, mu = 1e-04, control = list(),
 method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
 outer.iterations = 100, outer.eps = 1e-05, ...,
 hessian = FALSE)
```

**Arguments**

|                                                                   |                                                                                                                                                                    |
|-------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>theta</code>                                                | numeric (vector) starting value (of length $p$ ): must be in the feasible region.                                                                                  |
| <code>f</code>                                                    | function to minimise (see below).                                                                                                                                  |
| <code>grad</code>                                                 | gradient of <code>f</code> (a <code>function</code> as well), or <code>NULL</code> (see below).                                                                    |
| <code>ui</code>                                                   | constraint matrix ( $k \times p$ ), see below.                                                                                                                     |
| <code>ci</code>                                                   | constraint vector of length $k$ (see below).                                                                                                                       |
| <code>mu</code>                                                   | (Small) tuning parameter.                                                                                                                                          |
| <code>control</code> , <code>method</code> , <code>hessian</code> | passed to <code>optim</code> .                                                                                                                                     |
| <code>outer.iterations</code>                                     | iterations of the barrier algorithm.                                                                                                                               |
| <code>outer.eps</code>                                            | non-negative number; the relative convergence tolerance of the barrier algorithm.                                                                                  |
| <code>...</code>                                                  | Other named arguments to be passed to <code>f</code> and <code>grad</code> : needs to be passed through <code>optim</code> so should not match its argument names. |

**Details**

The feasible region is defined by `ui %*% theta - ci >= 0`. The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then `optim` is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter `mu` multiplies the barrier term. Its precise value is often relatively unimportant. As `mu` increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any `optim` method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B").

The objective function `f` takes as first argument the vector of parameters over which minimisation is to take place. It should return a scalar result. Optional arguments `...` will be passed to `optim`

and then (if not used by `optim`) to `f`. As with `optim`, the default is to minimise, but maximisation can be performed by setting `control$fnScale` to a negative value.

The gradient function `grad` must be supplied except with `method = "Nelder-Mead"`. It should take arguments matching those of `f` and return a vector containing the gradient.

### Value

As for `optim`, but with two extra components: `barrier.value` giving the value of the barrier function at the optimum and `outer.iterations` gives the number of outer iterations (calls to `optim`). The `counts` component contains the *sum* of all `optim()$counts`.

### See Also

`optim`, especially `method = "L-BFGS-B"` which does box-constrained optimisation.

### Examples

```
from optim
fr <- function(x) { ## Rosenbrock Banana function
 x1 <- x[1]
 x2 <- x[2]
 100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) { ## Gradient of fr
 x1 <- x[1]
 x2 <- x[2]
 c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
 200 * (x2 - x1 * x1))
}

optim(c(-1.2,1), fr, grr)
#Box-constraint, optimum on the boundary
constrOptim(c(-1.2,0.9), fr, grr, ui = rbind(c(-1,0), c(0,-1)), ci = c(-1,-1))
x <= 0.9, y - x > 0.1
constrOptim(c(.5,0), fr, grr, ui = rbind(c(-1,0), c(1,-1)), ci = c(-0.9,0.1))

Solves linear and quadratic programming problems
but needs a feasible starting value
#
from example(solve.QP) in quadprog
no derivative
fQP <- function(b) {-sum(c(0,5,0)*b)+0.5*sum(b*b)}
Amat <- matrix(c(-4,-3,0,2,1,0,0,-2,1), 3, 3)
bvec <- c(-8, 2, 0)
constrOptim(c(2,-1,-1), fQP, NULL, ui = t(Amat), ci = bvec)
derivative
gQP <- function(b) {-c(0, 5, 0) + b}
constrOptim(c(2,-1,-1), fQP, gQP, ui = t(Amat), ci = bvec)

Now with maximisation instead of minimisation
hQP <- function(b) {sum(c(0,5,0)*b)-0.5*sum(b*b)}
```

```
constrOptim(c(2,-1,-1), hQP, NULL, ui = t(Amat), ci = bvec,
 control = list(fnscale = -1))
```

**contrast***(Possibly Sparse) Contrast Matrices***Description**

Return a matrix of contrasts.

**Usage**

```
contr.helmert(n, contrasts = TRUE, sparse = FALSE)
contr.poly(n, scores = 1:n, contrasts = TRUE, sparse = FALSE)
contr.sum(n, contrasts = TRUE, sparse = FALSE)
contr.treatment(n, base = 1, contrasts = TRUE, sparse = FALSE)
contr.SAS(n, contrasts = TRUE, sparse = FALSE)
```

**Arguments**

|                        |                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>n</code>         | a vector of levels for a factor, or the number of levels.                                                           |
| <code>contrasts</code> | a logical indicating whether contrasts should be computed.                                                          |
| <code>sparse</code>    | logical indicating if the result should be sparse (of class <code>dgCMatrix</code> ), using package <b>Matrix</b> . |
| <code>scores</code>    | the set of values over which orthogonal polynomials are to be computed.                                             |
| <code>base</code>      | an integer specifying which group is considered the baseline group. Ignored if <code>contrasts</code> is FALSE.     |

**Details**

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with `n` levels. The returned value contains the computed contrasts. If the argument `contrasts` is FALSE a square indicator matrix (the dummy coding) is returned **except** for `contr.poly` (which includes the 0-degree, i.e. constant, polynomial when `contrasts = FALSE`).

`contr.helmert` returns Helmert contrasts, which contrast the second level with the first, the third with the average of the first two, and so on. `contr.poly` returns contrasts based on orthogonal polynomials. `contr.sum` uses ‘sum to zero contrasts’.

`contr.treatment` contrasts each level with the baseline level (specified by `base`): the baseline level is omitted. Note that this does not produce ‘contrasts’ as defined in the standard theory for linear models as they are not orthogonal to the intercept.

`contr.SAS` is a wrapper for `contr.treatment` that sets the base level to be the last level of the factor. The coefficients produced when using these contrasts should be equivalent to those produced by many (but not all) SAS procedures.

For consistency, `sparse` is an argument to all these contrast functions, however `sparse = TRUE` for `contr.poly` is typically pointless and is rarely useful for `contr.helmert`.

### Value

A matrix with n rows and k columns, with k=n-1 if contrasts is TRUE and k=n if contrasts is FALSE.

### Examples

```
(cH <- contr.helmert(4))
apply(cH, 2, sum) # column sums are 0
crossprod(cH) # diagonal -- columns are orthogonal
contr.helmert(4, contrasts = FALSE) # just the 4 x 4 identity matrix

(cT <- contr.treatment(5))
all(crossprod(cT) == diag(4)) # TRUE: even orthonormal

(cT. <- contr.SAS(5))
all(crossprod(cT.) == diag(4)) # TRUE

zapsmall(cP <- contr.poly(3)) # Linear and Quadratic
zapsmall(crossprod(cP), digits = 15) # orthonormal up to fuzz
```

## contrasts

### *Get and Set Contrast Matrices*

### Description

Set and view the contrasts associated with a factor.

### Usage

```
contrasts(x, contrasts = TRUE, sparse = FALSE)
contrasts(x, how.many) <- value
```

### Arguments

|           |                                                                                                                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | a factor or a logical variable.                                                                                                                                                                                                                                            |
| contrasts | logical. See ‘Details’.                                                                                                                                                                                                                                                    |
| sparse    | logical indicating if the result should be sparse (of class <a href="#">dgCMatrix</a> ), using package <a href="#">Matrix</a> .                                                                                                                                            |
| how.many  | How many contrasts should be made. Defaults to one less than the number of levels of x. This need not be the same as the number of columns of value.                                                                                                                       |
| value     | either a numeric matrix (or a sparse or dense matrix of a class extending <a href="#">dMatrix</a> from package <a href="#">Matrix</a> ) whose columns give coefficients for contrasts in the levels of x, or the (quoted) name of a function which computes such matrices. |

## Details

If contrasts are not set for a factor the default functions from `options("contrasts")` are used.

A logical vector `x` is converted into a two-level factor with levels `c(FALSE, TRUE)` (regardless of which levels occur in the variable).

The argument `contrasts` is ignored if `x` has a matrix `contrasts` attribute set. Otherwise if `contrasts = TRUE` it is passed to a `contrasts` function such as `contr.treatment` and if `contrasts = FALSE` an identity matrix is returned. Suitable functions have a first argument which is the character vector of levels, a named argument `contrasts` (always called with `contrasts = TRUE`) and optionally from R 2.10.0 a logical argument `sparse`.

If `value` supplies more than `how.many` contrasts, the first `how.many` are used. If too few are supplied, a suitable contrast matrix is created by extending `value` after ensuring its columns are contrasts (orthogonal to the constant term) and not collinear.

## Examples

```
utils::example(factor)
fff <- ff[, drop = TRUE] # reduce to 5 levels.
contrasts(fff) # treatment contrasts by default
contrasts(C(fff, sum))
contrasts(fff, contrasts = FALSE) # the 5x5 identity matrix

contrasts(fff) <- contr.sum(5); contrasts(fff) # set sum contrasts
contrasts(fff, 2) <- contr.sum(5); contrasts(fff) # set 2 contrasts
supply 2 contrasts, compute 2 more to make full set of 4.
contrasts(fff) <- contr.sum(5)[, 1:2]; contrasts(fff)

using sparse contrasts: % useful, once model.matrix() works with these :
ffs <- fff
contrasts(ffs) <- contr.sum(5, sparse = TRUE)[, 1:2]; contrasts(ffs)
stopifnot(all.equal(ffs, fff))
contrasts(ffs) <- contr.sum(5, sparse = TRUE); contrasts(ffs)
```

## Description

Use the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

## Usage

```
convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))
```

### Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code> | numeric sequences <i>of the same length</i> to be convolved.                                                                                                                                                                                                                                                                                                                                                                              |
| <code>conj</code> | logical; if TRUE, take the complex <i>conjugate</i> before back-transforming (default, and used for usual convolution).                                                                                                                                                                                                                                                                                                                   |
| <code>type</code> | character; one of "circular", "open", "filter" (beginning of word is ok). For <code>circular</code> , the two sequences are treated as <i>circular</i> , i.e., periodic.<br>For <code>open</code> and <code>filter</code> , the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of <code>x</code> with weights <code>y</code> . |

### Details

The Fast Fourier Transform, [fft](#), is used for efficiency.

The input sequences `x` and `y` must have the same length if `circular` is true.

Note that the usual definition of convolution of two sequences `x` and `y` is given by `convolve(x, rev(y), type = "o")`.

### Value

If `r <- convolve(x, y, type = "open")` and `n <- length(x), m <- length(y)`, then

$$r_k = \sum_i x_{k-m+i} y_i$$

where the sum is over all valid indices  $i$ , for  $k = 1, \dots, n + m - 1$ .

If `type == "circular"`,  $n = m$  is required, and the above is true for  $i, k = 1, \dots, n$  when  $x_j := x_{n+j}$  for  $j < 1$ .

### See Also

[fft](#), [nextn](#), and particularly [filter](#) (from the `stats` package) which may be more appropriate.

### Examples

```
require(graphics)

x <- c(0,0,0,100,0,0,0)
y <- c(0,0,1, 2 ,1,0,0)/4
zapsmall(convolve(x, y)) # *NOT* what you first thought.
zapsmall(convolve(x, y[3:5], type = "f")) # rather
x <- rnorm(50)
y <- rnorm(50)
Circular convolution *has* this symmetry:
all.equal(convolve(x, y, conj = FALSE), rev(convolve(rev(y), x)))

n <- length(x <- -20:24)
y <- (x-10)^2/1000 + rnorm(x)/8
```

```

Han <- function(y) # Hanning
 convolve(y, c(1,2,1)/4, type = "filter")

plot(x, y, main = "Using convolve(.) for Hanning filters")
lines(x[-c(1 , n)], Han(y), col = "red")
lines(x[-c(1:2, (n-1):n)], Han(Han(y)), lwd = 2, col = "dark blue")

```

cophenetic

*Cophenetic Distances for a Hierarchical Clustering*

## Description

Computes the cophenetic distances for a hierarchical clustering.

## Usage

```

cophenetic(x)
Default S3 method:
cophenetic(x)
S3 method for class dendrogram
cophenetic(x)

```

## Arguments

- x an R object representing a hierarchical clustering. For the default method, an object of class "[hclust](#)" or with a method for [as.hclust\(\)](#) such as "[agnes](#)" in package [cluster](#).

## Details

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

`cophenetic` is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an [as.hclust\(\)](#) or, more directly, a `cophenetic()` method for such a class.

The method for objects of class "[dendrogram](#)" requires that all leaves of the dendrogram object have non-null labels.

## Value

An object of class "[dist](#)".

## Author(s)

Robert Gentleman

## Examples

```
require(graphics)

d1 <- dist(USArrests)
hc <- hclust(d1, "ave")
d2 <- cophenetic(hc)
cor(d1, d2) # 0.7659

Example from Sneath & Sokal, Fig. 5-29, p.279
d0 <- c(1,3.8,4.4,5.1, 4,4.2,5, 2.6,5.3, 5.4)
attributes(d0) <- list(Size = 5, diag = TRUE)
class(d0) <- "dist"
names(d0) <- letters[1:5]
d0
utils::str(upgma <- hclust(d0, method = "average"))
plot(upgma, hang = -1)
#
(d.coph <- cophenetic(upgma))
cor(d0, d.coph) # 0.9911
```

## Description

`var`, `cov` and `cor` compute the variance of `x` and the covariance or correlation of `x` and `y` if these are vectors. If `x` and `y` are matrices then the covariances (or correlations) between the columns of `x` and the columns of `y` are computed.

`cov2cor` scales a covariance matrix into the corresponding correlation matrix *efficiently*.

## Usage

```
var(x, y = NULL, na.rm = FALSE, use)

cov(x, y = NULL, use = "everything",
 method = c("pearson", "kendall", "spearman"))

cor(x, y = NULL, use = "everything",
 method = c("pearson", "kendall", "spearman"))

cov2cor(V)
```

## Arguments

|        |                                                                                                                                                                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a numeric vector, matrix or data frame.                                                                                                                                                                                                               |
| y      | NULL (default) or a vector, matrix or data frame with compatible dimensions to x. The default is equivalent to $y = x$ (but more efficient).                                                                                                          |
| na.rm  | logical. Should missing values be removed?                                                                                                                                                                                                            |
| use    | an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs". |
| method | a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman", can be abbreviated.                                                                              |
| v      | symmetric numeric matrix, usually positive definite such as a covariance matrix.                                                                                                                                                                      |

## Details

For cov and cor one must *either* give a matrix or data frame for x or give both x and y.

The inputs must be numeric (as determined by `is.numeric`: logical values are also allowed for historical compatibility): the "kendall" and "spearman" methods make sense for ordered inputs but `xtfrm` can be used to find a suitable prior transformation to numbers.

`var` is just another interface to `cov`, where `na.rm` is used to determine the default for use when that is unspecified. If `na.rm` is TRUE then the complete observations (rows) are used (`use = "na.or.complete"`) to compute the variance. Otherwise, by default `use = "everything"`.

If `use` is "everything", `NAs` will propagate conceptually, i.e., a resulting value will be NA whenever one of its contributing observations is NA.

If `use` is "all.obs", then the presence of missing observations will produce an error. If `use` is "complete.obs" then missing values are handled by casewise deletion (and if there are no complete cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives NA. Finally, if `use` has the value "pairwise.complete.obs" then the correlation or covariance between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite, as well as NA entries if there are no complete pairs for that pair of variables. For `cov` and `var`, "pairwise.complete.obs" only works with the "pearson" method. Note that (the equivalent of) `var(double(0), use = *)` gives NA for `use = "everything"` and "na.or.complete", and gives an error in the other cases.

The denominator  $n - 1$  is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return `NA` when there is only one observation (whereas S-PLUS has been returning `NaN`), and fail if x has length zero.

For `cor()`, if `method` is "kendall" or "spearman", Kendall's  $\tau$  or Spearman's  $\rho$  statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For `cov()`, a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes `cor(R(x), R(y))` (or `cov(., .)`) where `R(u) := rank(u, na.last = "keep")`. In the case of missing values, the ranks are calculated depending on the value of `use`, either based on complete observations, or based on pairwise completeness with reranking for each pair.

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently

by using `sweep(., FUN = "/")` twice. The `cov2cor` function is even a bit more efficient, and provided mostly for didactical reasons.

### Value

For `r <- cor(*, use = "all.obs")`, it is now guaranteed that `all(r <= 1)`.

### Note

Some people have noted that the code for Kendall's tau is slow for very large datasets (many more than 1000 cases). It rarely makes sense to do such a computation, but see function `cor.fk` in package **pcaPP**.

### References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

### See Also

`cor.test` for confidence intervals (and tests).  
`cov.wt` for *weighted* covariance computation.  
`sd` for standard deviation (vectors).

### Examples

```
var(1:10) # 9.166667

var(1:5, 1:5) # 2.5

Two simple vectors
cor(1:10, 2:11) # == 1

Correlation Matrix of Multivariate sample:
(Cl <- cor(longley))
Graphical Correlation Matrix:
symnum(Cl) # highly correlated

Spearmans rho and Kendalls tau
symnum(cLS <- cor(longley, method = "spearman"))
symnum(cLK <- cor(longley, method = "kendall"))
How much do they differ?
i <- lower.tri(Cl)
cor(cbind(P = Cl[i], S = cLS[i], K = cLK[i]))

cov2cor() scales a covariance matrix by its diagonal
to become the correlation matrix.
cov2cor # see the function definition {and learn ..}
stopifnot(all.equal(Cl, cov2cor(cov(longley))),
 all.equal(cor(longley, method = "kendall"),
 cov2cor(cov(longley, method = "kendall"))))

####--- Missing value treatment:
```

```

C1 <- cov(swiss)
range(eigen(C1, only.values = TRUE)$values) # 6.19 1921

swM := "swiss" with 3 "missing"s :
swM <- swiss
colnames(swM) <- abbreviate(colnames(swiss), min=6)
swM[1,2] <- swM[7,3] <- swM[25,5] <- NA # create 3 "missing"

Consider all 5 "use" cases :
(C. <- cov(swM)) # use="everything" quite a few NAs in cov.matrix
try(cov(swM, use = "all")) # Error: missing obs...
C2 <- cov(swM, use = "complete")
stopifnot(identical(C2, cov(swM, use = "na.or.complete")))
range(eigen(C2, only.values = TRUE)$values) # 6.46 1930
C3 <- cov(swM, use = "pairwise")
range(eigen(C3, only.values = TRUE)$values) # 6.19 1938

Kendalls tau doesnt change much:
symnum(Rc <- cor(swM, method = "kendall", use = "complete"))
symnum(Rp <- cor(swM, method = "kendall", use = "pairwise"))
symnum(R. <- cor(swiss, method = "kendall"))

"pairwise" is closer componentwise,
summary(abs(c(1 - Rp/R.)))
summary(abs(c(1 - Rc/R.)))

but "complete" is closer in Eigen space:
EV <- function(m) eigen(m, only.values=TRUE)$values
summary(abs(1 - EV(Rp)/EV(R.)) / abs(1 - EV(Rc)/EV(R.)))

```

**cor.test***Test for Association/Correlation Between Paired Samples***Description**

Test for association between paired samples, using one of Pearson's product moment correlation coefficient, Kendall's  $\tau$  or Spearman's  $\rho$ .

**Usage**

```

cor.test(x, ...)

Default S3 method:
cor.test(x, y,
 alternative = c("two.sided", "less", "greater"),
 method = c("pearson", "kendall", "spearman"),
 exact = NULL, conf.level = 0.95, continuity = FALSE, ...)

S3 method for class formula
cor.test(formula, data, subset, na.action, ...)

```

### Arguments

|                          |                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>        | numeric vectors of data values. <code>x</code> and <code>y</code> must have the same length.                                                                                                                            |
| <code>alternative</code> | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. "greater" corresponds to positive association, "less" to negative association.       |
| <code>method</code>      | a character string indicating which correlation coefficient is to be used for the test. One of "pearson", "kendall", or "spearman", can be abbreviated.                                                                 |
| <code>exact</code>       | a logical indicating whether an exact p-value should be computed. Used for Kendall's $\tau$ and Spearman's $\rho$ . See 'Details' for the meaning of <code>NULL</code> (the default).                                   |
| <code>conf.level</code>  | confidence level for the returned confidence interval. Currently only used for the Pearson product moment correlation coefficient if there are at least 4 complete pairs of observations.                               |
| <code>continuity</code>  | logical: if true, a continuity correction is used for Kendall's $\tau$ and Spearman's $\rho$ when not computed exactly.                                                                                                 |
| <code>formula</code>     | a formula of the form $\sim u + v$ , where each of <code>u</code> and <code>v</code> are numeric variables giving the data values for one sample. The samples must be of the same length.                               |
| <code>data</code>        | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>      | an optional vector specifying a subset of observations to be used.                                                                                                                                                      |
| <code>na.action</code>   | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                              |
| <code>...</code>         | further arguments to be passed to or from methods.                                                                                                                                                                      |

### Details

The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range  $[-1, 1]$  with 0 indicating no association. These are sometimes referred to as tests of no *correlation*, but that term is often confined to the default method.

If `method` is "pearson", the test statistic is based on Pearson's product moment correlation coefficient `cor(x, y)` and follows a t distribution with `length(x)-2` degrees of freedom if the samples follow independent normal distributions. If there are at least 4 complete pairs of observation, an asymptotic confidence interval is given based on Fisher's Z transform.

If `method` is "kendall" or "spearman", Kendall's  $\tau$  or Spearman's  $\rho$  statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall's test, by default (if `exact` is `NULL`), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman's test, p-values are computed using algorithm AS 89 for  $n < 1290$  and `exact = TRUE`, otherwise via the asymptotic t approximation. Note that these are 'exact' for  $n < 10$ , and use an Edgeworth series approximation for larger sample sizes (the cutoff has been changed from the original paper).

### Value

A list with class "htest" containing the following components:

|                          |                                                                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the test statistic.                                                                                                                                                      |
| <code>parameter</code>   | the degrees of freedom of the test statistic in the case that it follows a t distribution.                                                                                            |
| <code>p.value</code>     | the p-value of the test.                                                                                                                                                              |
| <code>estimate</code>    | the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed.                                                                          |
| <code>null.value</code>  | the value of the association measure under the null hypothesis, always 0.                                                                                                             |
| <code>alternative</code> | a character string describing the alternative hypothesis.                                                                                                                             |
| <code>method</code>      | a character string indicating how the association was measured.                                                                                                                       |
| <code>data.name</code>   | a character string giving the names of the data.                                                                                                                                      |
| <code>conf.int</code>    | a confidence interval for the measure of association. Currently only given for Pearson's product moment correlation coefficient in case of at least 4 complete pairs of observations. |

### Examples

```
Hollander & Wolfe (1973), p. 187f.
Assessment of tuna quality. We compare the Hunter L measure of
lightness to the averages of consumer panel scores (recoded as
integer values from 1 to 6 and averaged over 80 such values) in
9 lots of canned tuna.

x <- c(44.4, 45.9, 41.9, 53.3, 44.7, 44.1, 50.7, 45.2, 60.1)
y <- c(2.6, 3.1, 2.5, 5.0, 3.6, 4.0, 5.2, 2.8, 3.8)

The alternative hypothesis of interest is that the
Hunter L value is positively associated with the panel score.

cor.test(x, y, method = "kendall", alternative = "greater")
=> p=0.05972

cor.test(x, y, method = "kendall", alternative = "greater",
 exact = FALSE) # using large sample approximation
=> p=0.04765
```

```

Compare this to
cor.test(x, y, method = "spearm", alternative = "g")
cor.test(x, y, alternative = "g")

Formula interface.
require(graphics)
pairs(USJudgeRatings)
cor.test(~ CONT + INTG, data = USJudgeRatings)

```

cov.wt

*Weighted Covariance Matrices*

## Description

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.

## Usage

```
cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE,
 method = c("unbiased", "ML"))
```

## Arguments

- |        |                                                                                                                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a matrix or data frame. As usual, rows are observations and columns are variables.                                                                                                                                                                        |
| wt     | a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of x.                                                                                                                                        |
| cor    | a logical indicating whether the estimated correlation weighted matrix will be returned as well.                                                                                                                                                          |
| center | either a logical or a numeric vector specifying the centers to be used when computing covariances. If TRUE, the (weighted) mean of each variable is used, if FALSE, zero is used. If center is numeric, its length must equal the number of columns of x. |
| method | string specifying how the result is scaled, see ‘Details’ below.                                                                                                                                                                                          |

## Details

By default, `method = "unbiased"`, The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default ( $1/n$ ) the conventional unbiased estimate of the covariance matrix with divisor ( $n - 1$ ) is obtained. This differs from the behaviour in S-PLUS which corresponds to `method = "ML"` and does not divide.

## Value

A list containing the following named components:

- |        |                                                                            |
|--------|----------------------------------------------------------------------------|
| cov    | the estimated (weighted) covariance matrix                                 |
| center | an estimate for the center (mean) of the data.                             |
| n.obs  | the number of observations (rows) in x.                                    |
| wt     | the weights used in the estimation. Only returned if given as an argument. |
| cor    | the estimated correlation matrix. Only returned if cor is TRUE.            |

**See Also**

[cov](#) and [var](#).

**Examples**

```
(xy <- cbind(x = 1:10, y = c(1:3, 8:5, 8:10)))
w1 <- c(0,0,0,1,1,1,1,1,0,0)
cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)
```

**cpgram**

*Plot Cumulative Periodogram*

**Description**

Plots a cumulative periodogram.

**Usage**

```
cpgram(ts, taper = 0.1,
 main = paste("Series: ", deparse(substitute(ts))),
 ci.col = "blue")
```

**Arguments**

|               |                                               |
|---------------|-----------------------------------------------|
| <b>ts</b>     | a univariate time series                      |
| <b>taper</b>  | proportion tapered in forming the periodogram |
| <b>main</b>   | main title                                    |
| <b>ci.col</b> | colour for confidence band.                   |

**Value**

None.

**Side Effects**

Plots the cumulative periodogram in a square plot.

**Note**

From package **MASS**.

**Author(s)**

B.D. Ripley

## Examples

```
require(graphics)

par(pty = "s", mfrow = c(1,2))
cpgram(lh)
lh.ar <- ar(lh, order.max = 9)
cpgram(lh.ar$resid, main = "AR(3) fit to lh")

cpgram(ldeaths)
```

---

cutree

*Cut a Tree into Groups of Data*

---

## Description

Cuts a tree, e.g., as resulting from [hclust](#), into several groups either by specifying the desired number(s) of groups or the cut height(s).

## Usage

```
cutree(tree, k = NULL, h = NULL)
```

## Arguments

|      |                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tree | a tree as produced by <a href="#">hclust</a> . <code>cutree()</code> only expects a list with components <code>merge</code> , <code>height</code> , and <code>labels</code> , of appropriate content each. |
| k    | an integer scalar or vector with the desired number of groups                                                                                                                                              |
| h    | numeric scalar or vector with heights where the tree should be cut. At least one of <code>k</code> or <code>h</code> must be specified, <code>k</code> overrides <code>h</code> if both are given.         |

## Details

Cutting trees at a given height is only possible for ultrametric trees (with monotone clustering heights).

## Value

`cutree` returns a vector with group memberships if `k` or `h` are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of `k` or `h`, respectively (which are also used as column names).

## References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

## See Also

[hclust](#), [dendrogram](#) for cutting trees themselves.

## Examples

```
hc <- hclust(dist(USArrests))

cutree(hc, k = 1:5) #k = 1 is trivial
cutree(hc, h = 250)

Compare the 2 and 4 grouping:
g24 <- cutree(hc, k = c(2,4))
table(grp2 = g24[, "2"], grp4 = g24[, "4"])
```

decompose

*Classical Seasonal Decomposition by Moving Averages*

## Description

Decompose a time series into seasonal, trend and irregular components using moving averages.  
Deals with additive or multiplicative seasonal component.

## Usage

```
decompose(x, type = c("additive", "multiplicative"), filter = NULL)
```

## Arguments

|                     |                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | A time series.                                                                                                                                                                                                   |
| <code>type</code>   | The type of seasonal component. Can be abbreviated.                                                                                                                                                              |
| <code>filter</code> | A vector of filter coefficients in reverse time order (as for AR or MA coefficients), used for filtering out the seasonal component. If <code>NULL</code> , a moving average with symmetric window is performed. |

## Details

The additive model used is:

$$Y_t = T_t + S_t + e_t$$

The multiplicative model used is:

$$Y_t = T_t S_t e_t$$

The function first determines the trend component using a moving average (if `filter` is `NULL`, a symmetric window with equal weights is used), and removes it from the time series. Then, the seasonal figure is computed by averaging, for each time unit, over all periods. The seasonal figure is then centered. Finally, the error component is determined by removing trend and seasonal figure (recycled as needed) from the original time series.

This only works well if `x` covers an integer number of complete periods.

**Value**

An object of class "decomposed.ts" with following components:

|          |                                                              |
|----------|--------------------------------------------------------------|
| x        | The original series. (Only since R 2.14.0.)                  |
| seasonal | The seasonal component (i.e., the repeated seasonal figure). |
| figure   | The estimated seasonal figure only.                          |
| trend    | The trend component.                                         |
| random   | The remainder part.                                          |
| type     | The value of type.                                           |

**Note**

The function [stl](#) provides a much more sophisticated decomposition.

x <- ts(x, start = c(1951, 1), end = c(1958, 4), frequency = 4)
m <- decompose(x)
seasonal figure: 6.25, 8.62, -8.84, -6.03
round(decompose(x)$figure / 10, 2)
```

**delete.response**      *Modify Terms Objects*

### Description

`delete.response` returns a `terms` object for the same model but with no response variable.  
`drop.terms` removes variables from the right-hand side of the model. There is also a "[.terms" method to perform the same function (with `keep.response = TRUE`).  
`reformulate` creates a formula from a character vector.

### Usage

```
delete.response(termobj)

reformulate(termlabels, response = NULL, intercept = TRUE)

drop.terms(termobj, dropx = NULL, keep.response = FALSE)
```

### Arguments

|                            |                                                                                                       |
|----------------------------|-------------------------------------------------------------------------------------------------------|
| <code>termobj</code>       | A <code>terms</code> object                                                                           |
| <code>termlabels</code>    | character vector giving the right-hand side of a model formula. Cannot be zero-length.                |
| <code>response</code>      | character string, symbol or call giving the left-hand side of a model formula, or <code>NULL</code> . |
| <code>intercept</code>     | logical: should the formula have an intercept? New in R 2.13.0.                                       |
| <code>dropx</code>         | vector of positions of variables to drop from the right-hand side of the model.                       |
| <code>keep.response</code> | Keep the response in the resulting object?                                                            |

### Value

`delete.response` and `drop.terms` return a `terms` object.  
`reformulate` returns a formula.

### See Also

[terms](#)

### Examples

```
ff <- y ~ z + x + w
tt <- terms(ff)
tt
delete.response(tt)
drop.terms(tt, 2:3, keep.response = TRUE)
tt[-1]
tt[2:3]
reformulate(attr(tt, "term.labels"))

keep LHS :
```

```

reformulate("x*w", ff[[2]])
fS <- surv(ft, case) ~ a + b
reformulate(c("a", "b*f"), fS[[2]])

using non-syntactic names:
reformulate(c("P/E", "% Growth"), response = as.name("+-"))

stopifnot(identical(~ var, reformulate("var")),
 identical(~ a + b + c, reformulate(letters[1:3])),
 identical(y ~ a + b, reformulate(letters[1:2], "y"))
)

```

**dendrapply***Apply a Function to All Nodes of a Dendrogram***Description**

Apply function FUN to each node of a [dendrogram](#) recursively. When  $y \leftarrow \text{dendrapply}(x, \text{fn})$ , then  $y$  is a dendrogram of the same graph structure as  $x$  and for each node,  $y.\text{node}[j] \leftarrow \text{FUN}(x.\text{node}[j], \dots)$  (where  $y.\text{node}[j]$  is an (invalid!) notation for the  $j$ -th node of  $y$ ).

**Usage**

```
dendrapply(X, FUN, ...)
```

**Arguments**

- |     |                                                                                                                                                                |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X   | an object of class " <a href="#">dendrogram</a> ".                                                                                                             |
| FUN | an R function to be applied to each dendrogram node, typically working on its <a href="#">attributes</a> alone, returning an altered version of the same node. |
| ... | potential further arguments passed to FUN.                                                                                                                     |

**Value**

Usually a dendrogram of the same (graph) structure as X. For that, the function must be conceptually of the form  $\text{FUN} \leftarrow \text{function}(X) \{ \text{attributes}(X) \leftarrow \dots; \text{X} \}$ , i.e. returning the node with some attributes added or changed.

**Note**

this is still somewhat experimental, and suggestions for enhancements (or nice examples of usage) are very welcome.

**Author(s)**

Martin Maechler

**See Also**

[as.dendrogram](#), [lapply](#) for applying a function to each component of a list, [rapply](#) for doing so to each non-list component of a nested list.

## Examples

```
require(graphics)

a smallish simple dendrogram
dhc <- as.dendrogram(hc <- hclust(dist(USArrests), "ave"))
(dhc21 <- dhc[[2]][[1]])

too simple:
dendrapply(dhc21, function(n) utils::str(attributes(n)))

toy example to set colored leaf labels :
local({
 colLab <- function(n) {
 if(is.leaf(n)) {
 a <- attributes(n)
 i <- i+1
 attr(n, "nodePar") <-
 c(a$nodePar, list(lab.col = mycols[i], lab.font = i%%3))
 }
 n
 }
 mycols <- grDevices::rainbow(attr(dhc21, "members"))
 i <- 0
})
dl <- dendrapply(dhc21, colLab)
op <- par(mfrow = 2:1)
plot(dhc21)
plot(dl) ## --> colored labels!
par(op)
```

## Description

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.

## Usage

```
as.dendrogram(object, ...)
S3 method for class hclust
as.dendrogram(object, hang = -1, ...)

S3 method for class dendrogram
as.hclust(x, ...)

S3 method for class dendrogram
plot(x, type = c("rectangle", "triangle"),
 center = FALSE,
 edge.root = is.leaf(x) || !is.null(attr(x, "edgetext")),
 nodePar = NULL, edgePar = list(),
```

```

leaflab = c("perpendicular", "textlike", "none"),
dLeaf = NULL, xlab = "", ylab = "", xaxt = "n", yaxt = "s",
horiz = FALSE, frame.plot = FALSE, xlim, ylim, ...)

S3 method for class dendrogram
cut(x, h, ...)

S3 method for class dendrogram
merge(x, y, ..., height)

S3 method for class dendrogram
print(x, digits, ...)

S3 method for class dendrogram
rev(x)

S3 method for class dendrogram
str(object, max.level = NA, digits.d = 3,
 give.attr = FALSE, wid =getOption("width"),
 nest.lev = 0, indent.str = "",
 last.str =getOption("str.dendrogram.last"), stem = "--",
 ...)

is.leaf(object)

```

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | any R object that can be made into one of class "dendrogram".                                                                                                                                                                                                                                                                                                                                                                  |
| x, y      | object(s) of class "dendrogram".                                                                                                                                                                                                                                                                                                                                                                                               |
| hang      | numeric scalar indicating how the <i>height</i> of leaves should be computed from the heights of their parents; see <a href="#">plot.hclust</a> .                                                                                                                                                                                                                                                                              |
| type      | type of plot.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| center    | logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.                                                                                                                                                                                                                                                                 |
| edge.root | logical; if true, draw an edge to the root node.                                                                                                                                                                                                                                                                                                                                                                               |
| nodePar   | a list of plotting parameters to use for the nodes (see <a href="#">points</a> ) or NULL by default which does not draw symbols at the nodes. The list may contain components named pch, cex, col, xpd, and/or bg each of which can have length two for specifying separate attributes for <i>inner</i> nodes and <i>leaves</i> . Note that the default of pch is 1:2, so you may want to use pch = NA if you specify nodePar. |
| edgePar   | a list of plotting parameters to use for the edge <a href="#">segments</a> and labels (if there's an edgetext). The list may contain components named col, lty and lwd (for the segments), p.col, p.lwd, and p.lty (for the <a href="#">polygon</a> around the text) and t.col for the text color. As with nodePar, each can have length two for differentiating leaves and inner nodes.                                       |
| leaflab   | a string specifying how leaves are labeled. The default "perpendicular" write text vertically (by default).<br>"textlike" writes text horizontally (in a rectangle), and<br>"none" suppresses leaf labels.                                                                                                                                                                                                                     |
| dLeaf     | a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.                                                                                                                                                                                                                                                                 |

|                                                           |                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| horiz                                                     | logical indicating if the dendrogram should be drawn <i>horizontally</i> or not.                                                                                                                                                                                                        |
| frame.plot                                                | logical indicating if a box around the plot should be drawn, see <a href="#">plot.default</a> .                                                                                                                                                                                         |
| h                                                         | height at which the tree is cut.                                                                                                                                                                                                                                                        |
| height                                                    | height at which the two dendrogram should be merged. If not specified (or NULL), the default is ten percent larger than the (larger of the) two component heights.                                                                                                                      |
| xlim, ylim                                                | optional x- and y-limits of the plot, passed to <a href="#">plot.default</a> . The defaults for these show the full dendrogram.                                                                                                                                                         |
| ..., xlab, ylab, xaxt, yaxt                               | graphical parameters, or arguments for other methods.                                                                                                                                                                                                                                   |
| digits                                                    | integer specifying the precision for printing, see <a href="#">print.default</a> .                                                                                                                                                                                                      |
| max.level, digits.d, give.attr, wid, nest.lev, indent.str | arguments to <a href="#">str</a> , see <a href="#">str.default()</a> . Note that give.attr = FALSE still shows height and members attributes for each node.                                                                                                                             |
| last.str, stem                                            | strings used for <a href="#">str</a> () specifying how the last branch (at each level) should start and the <i>stem</i> to use for each dendrogram branch. In some environments, using last.str = "" will provide much nicer looking output, than the historical default last.str = "". |

## Details

The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree *z* is *z*[[1]], the second branch of the corresponding subtree is *z*[[1]][[2]], or shorter *z*[[c(1, 2)]], etc.. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only *members*, *height* and *leaf* for leaves are compulsory:

|          |                                                                                                                                                                                                                     |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| members  | total number of leaves in the branch                                                                                                                                                                                |
| height   | numeric non-negative height at which the node is plotted.                                                                                                                                                           |
| midpoint | numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for <code>plot(*, center = FALSE)</code> .                                 |
| label    | character; the label of the node                                                                                                                                                                                    |
| x.member | for <code>cut()\$upper</code> , the number of <i>former</i> members; more generally a substitute for the <i>members</i> component used for ‘horizontal’ (when <i>horiz</i> = FALSE, else ‘vertical’) alignment.     |
| edgetext | character; the label for the edge leading to the node                                                                                                                                                               |
| nodePar  | a named list (of length-1 components) specifying node-specific attributes for <a href="#">points</a> plotting, see the <i>nodePar</i> argument above.                                                               |
| edgePar  | a named list (of length-1 components) specifying attributes for <a href="#">segments</a> plotting of the edge leading to the node, and drawing of the edgetext if available, see the <i>edgePar</i> argument above. |
| leaf     | logical, if TRUE, the node is a leaf of the tree.                                                                                                                                                                   |

`cut.dendrogram()` returns a list with components *\$upper* and *\$lower*, the first is a truncated version of the original tree, also of class *dendrogram*, the latter a list with the branches obtained from cutting the tree, each a *dendrogram*.

There are [\[](#), [print](#), and [str](#) methods for “*dendrogram*” objects where the first one (extraction) ensures that selecting sub-branches keeps the class.

Objects of class “*hclust*” can be converted to class “*dendrogram*” using method `as.dendrogram()`, and since R 2.13.0, there is also a `as.hclust()` method as an inverse.

`rev.dendrogram` simply returns the dendrogram `x` with reversed nodes, see also [reorder.dendrogram](#).

The `merge(x, y, ...)` method which merges two or more dendrograms into a new one which has `x` and `y` (and optional further arguments) as branches.

`is.leaf(object)` returns logical indicating if `object` is a leaf (the most simple dendrogram).

`plotNode()` and `plotNodeLimit()` are helper functions.

### Warning

Some operations on dendrograms (including plotting) make use of recursion. For very deep trees It may be necessary to increase `options("expressions")`: if you do you are likely to need to set the C stack size larger than the default where possible.

### Note

`plot()`: When using `type = "triangle"`, `center = TRUE` often looks better.

`str(d)`: If you really want to see the *internal* structure, use `str(unclass(d))` instead.

### See Also

[dendrapply](#) for applying a function to *each* node. [order.dendrogram](#) and [reorder.dendrogram](#); further, the [labels](#) method.

### Examples

```
require(graphics); require(utils)

hc <- hclust(dist(USArrests), "ave")
(dend1 <- as.dendrogram(hc)) # "print()" method
str(dend1) # "str()" method
str(dend1, max = 2, last.str = "") # only the first two sub-levels
oo <- options(str.dendrogram.last = "\\") # yet another possibility
str(dend1, max = 2) # only the first two sub-levels
options(oo) # .. resetting them

op <- par(mfrow = c(2,2), mar = c(5,2,1,4))
plot(dend1)
"triangle" type and show inner nodes:
plot(dend1, nodePar = list(pch = c(1,NA), cex = 0.8, lab.cex = 0.8),
 type = "t", center = TRUE)
plot(dend1, edgePar = list(col = 1:2, lty = 2:3),
 dLeaf = 1, edge.root = TRUE)
plot(dend1, nodePar = list(pch = 2:1, cex = .4*2:1, col = 2:3),
 horiz = TRUE)

simple test for as.hclust() as the inverse of as.dendrogram():
stopifnot(identical(as.hclust(dend1)[1:4], hc[1:4]))

dend2 <- cut(dend1, h = 70)
plot(dend2$upper)
leaves are wrong horizontally:
plot(dend2$upper, nodePar = list(pch = c(1,7), col = 2:1))
dend2$lower is *NOT* a dendrogram, but a list of .. :
plot(dend2$lower[[3]], nodePar = list(col = 4), horiz = TRUE, type = "tr")
"inner" and "leaf" edges in different type & color :
```

```

plot(dend2$lower[[2]], nodePar = list(col = 1), # non empty list
 edgePar = list(lty = 1:2, col = 2:1), edge.root = TRUE)
par(op)
d3 <- dend2$lower[[2]][[2]][[1]]
stopifnot(identical(d3, dend2$lower[[2]][[c(2,1)]]))
str(d3, last.str = "")

merge() to join dendograms:
(d13 <- merge(dend2$lower[[1]], dend2$lower[[3]]))
merge() all parts back (using default height instead of original one):
den.1 <- Reduce(merge, dend2$lower)
or merge() all four parts at same height --> 4 branches (!)
d. <- merge(dend2$lower[[1]], dend2$lower[[2]], dend2$lower[[3]],
 dend2$lower[[4]])
(with a warning) or the same using do.call :
stopifnot(identical(d., do.call(merge, dend2$lower)))
plot(d., main = "merge(d1, d2, d3, d4) |-> dendrogram with a 4-split")

"Zoom" in to the first dendrogram :
plot(dend1, xlim = c(1,20), ylim = c(1,50))

nP <- list(col = 3:2, cex = c(2.0, 0.75), pch = 21:22,
 bg = c("light blue", "pink"),
 lab.cex = 0.75, lab.col = "tomato")
plot(d3, nodePar= nP, edgePar = list(col = "gray", lwd = 2), horiz = TRUE)

addE <- function(n) {
 if(!is.leaf(n)) {
 attr(n, "edgePar") <- list(p.col = "plum")
 attr(n, "edgetext") <- paste(attr(n,"members"), "members")
 }
 n
}
d3e <- dendrapply(d3, addE)
plot(d3e, nodePar = nP)
plot(d3e, nodePar = nP, leaflab = "textlike")

```

## Description

The (S3) generic function `density` computes kernel density estimates. Its default method does so with the given kernel and bandwidth for univariate observations.

## Usage

```

density(x, ...)
Default S3 method:
density(x, bw = "nrd0", adjust = 1,
 kernel = c("gaussian", "epanechnikov", "rectangular",

```

```

 "triangular", "biweight",
 "cosine", "optcosine"),
weights = NULL, window = kernel, width,
give.Rkern = FALSE,
n = 512, from, to, cut = 3, na.rm = FALSE, ...)

```

## Arguments

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>              | the data from which the estimate is to be computed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>bw</code>             | the smoothing bandwidth to be used. The kernels are scaled such that this is the standard deviation of the smoothing kernel. (Note this differs from the reference books cited below, and from S-PLUS.)<br><br><code>bw</code> can also be a character string giving a rule to choose the bandwidth. See <a href="#">bw.nrd</a> .<br><br>The default, "nrd0", has remained the default for historical and compatibility reasons, rather than as a general recommendation, where e.g., "SJ" would rather fit, see also V&R (2002). |
| <code>adjust</code>         | The specified (or computed) value of <code>bw</code> is multiplied by <code>adjust</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>kernel, window</code> | a character string giving the smoothing kernel to be used. This must be one of "gaussian", "rectangular", "triangular", "epanechnikov", "biweight", "cosine" or "optcosine", with default "gaussian", and may be abbreviated to a unique prefix (single letter).<br><br>"cosine" is smoother than "optcosine", which is the usual 'cosine' kernel in the literature and almost MSE-efficient. However, "cosine" is the version used by S.                                                                                         |
| <code>weights</code>        | numeric vector of non-negative observation weights, hence of same length as <code>x</code> . The default <code>NULL</code> is equivalent to <code>weights = rep(1/nx, nx)</code> where <code>nx</code> is the length of (the finite entries of) <code>x[]</code> .                                                                                                                                                                                                                                                                |
| <code>width</code>          | this exists for compatibility with S; if given, and <code>bw</code> is not, will set <code>bw</code> to <code>width</code> if this is a character string, or to a kernel-dependent multiple of <code>width</code> if this is numeric.                                                                                                                                                                                                                                                                                             |
| <code>give.Rkern</code>     | logical; if true, <i>no</i> density is estimated, and the 'canonical bandwidth' of the chosen kernel is returned instead.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>n</code>              | the number of equally spaced points at which the density is to be estimated. When <code>n &gt; 512</code> , it is rounded up to a power of 2 during the calculations (as <a href="#">fft</a> is used) and the final result is interpolated by <a href="#">approx</a> . So it almost always makes sense to specify <code>n</code> as a power of two.                                                                                                                                                                               |
| <code>from, to</code>       | the left and right-most points of the grid at which the density is to be estimated; the defaults are <code>cut * bw</code> outside of <code>range(x)</code> .                                                                                                                                                                                                                                                                                                                                                                     |
| <code>cut</code>            | by default, the values of <code>from</code> and <code>to</code> are cut bandwidths beyond the extremes of the data. This allows the estimated density to drop to approximately zero at the extremes.                                                                                                                                                                                                                                                                                                                              |
| <code>na.rm</code>          | logical; if TRUE, missing values are removed from <code>x</code> . If FALSE any missing values cause an error.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>...</code>            | further arguments for (non-default) methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Details

The algorithm used in `density.default` disperses the mass of the empirical distribution function over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this approximation with a discretized version of the kernel and then uses linear approximation to evaluate the density at the specified points.

The statistical properties of a kernel are determined by  $\sigma_K^2 = \int t^2 K(t) dt$  which is always  $= 1$  for our kernels (and hence the bandwidth `bw` is the standard deviation of the kernel) and  $R(K) = \int K^2(t) dt$ .

MSE-equivalent bandwidths (for different kernels) are proportional to  $\sigma_K R(K)$  which is scale invariant and for our kernels equal to  $R(K)$ . This value is returned when `give.Rkern = TRUE`. See the examples for using exact equivalent bandwidths.

Infinite values in `x` are assumed to correspond to a point mass at  $+\text{-Inf}$  and the density estimate is of the sub-density on  $(-\text{Inf}, +\text{Inf})$ .

## Value

If `give.Rkern` is true, the number  $R(K)$ , otherwise an object with class "density" whose underlying structure is a list containing the following components.

|                        |                                                                              |
|------------------------|------------------------------------------------------------------------------|
| <code>x</code>         | the <code>n</code> coordinates of the points where the density is estimated. |
| <code>y</code>         | the estimated density values. These will be non-negative, but can be zero.   |
| <code>bw</code>        | the bandwidth used.                                                          |
| <code>n</code>         | the sample size after elimination of missing values.                         |
| <code>call</code>      | the call which produced the result.                                          |
| <code>data.name</code> | the deparsed name of the <code>x</code> argument.                            |
| <code>has.na</code>    | logical, for compatibility (always FALSE).                                   |

The `print` method reports [summary](#) values on the `x` and `y` components.

## Description

Compute derivatives of simple expressions, symbolically.

## Usage

```
D (expr, name)
deriv(expr, ...)
deriv3(expr, ...)

Default S3 method:
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
 hessian = FALSE, ...)
S3 method for class formula
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
 hessian = FALSE, ...)

Default S3 method:
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
 hessian = TRUE, ...)
S3 method for class formula
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
 hessian = TRUE, ...)
```

### Arguments

|                                          |                                                                                                                                                                                                                           |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expr</code>                        | A <a href="#">expression</a> or <a href="#">call</a> or (except D) a formula with no lhs.                                                                                                                                 |
| <code>name</code> , <code>namevec</code> | character vector, giving the variable names (only one for D()) with respect to which derivatives will be computed.                                                                                                        |
| <code>function.arg</code>                | If specified and non-NULL, a character vector of arguments for a function return, or a function (with empty body) or TRUE, the latter indicating that a function with argument names <code>namevec</code> should be used. |
| <code>tag</code>                         | character; the prefix to be used for the locally created variables in result.                                                                                                                                             |
| <code>hessian</code>                     | a logical value indicating whether the second derivatives should be calculated and incorporated in the return value.                                                                                                      |
| <code>...</code>                         | arguments to be passed to or from methods.                                                                                                                                                                                |

### Details

D is modelled after its S namesake for taking simple symbolic derivatives.

`deriv` is a *generic* function with a default and a [formula](#) method. It returns a [call](#) for computing the `expr` and its (partial) derivatives, simultaneously. It uses so-called *algorithmic derivatives*. If `function.arg` is a function, its arguments can have default values, see the fx example below.

Currently, `deriv.formula` just calls `deriv.default` after extracting the expression to the right of `~`.

`deriv3` and its methods are equivalent to `deriv` and its methods except that `hessian` defaults to TRUE for `deriv3`.

The internal code knows about the arithmetic operators `+`, `-`, `*`, `/` and `^`, and the single-variable functions `exp`, `log`, `sin`, `cos`, `tan`, `sinh`, `cosh`, `sqrt`, `pnorm`, `dnorm`, `asin`, `acos`, `atan`, `gamma`, `lgamma`, `digamma` and `trigamma`, as well as `psigamma` for one or two arguments (but derivative only with respect to the first). (Note that only the standard normal distribution is considered.)

### Value

D returns a call and therefore can easily be iterated for higher derivatives.

`deriv` and `deriv3` normally return an [expression](#) object whose evaluation returns the function values with a "gradient" attribute containing the gradient matrix. If `hessian` is TRUE the evaluation also returns a "hessian" attribute containing the Hessian array.

If `function.arg` is not NULL, `deriv` and `deriv3` return a function with those arguments rather than an expression.

## Examples

```

formula argument :
dx2x <- deriv(~ x^2, "x") ; dx2x
Not run: expression({
 .value <- x^2
 .grad <- array(0, c(length(.value), 1), list(NULL, c("x")))
 .grad[, "x"] <- 2 * x
 attr(.value, "gradient") <- .grad
 .value
})
End(Not run)
mode(dx2x)
x <- -1:2
eval(dx2x)

Something tougher:
trig.exp <- expression(sin(cos(x + y^2)))
(D.sc <- D(trig.exp, "x"))
all.equal(D(trig.exp[[1]], "x"), D.sc)

(dxy <- deriv(trig.exp, c("x", "y")))
y <- 1
eval(dxy)
eval(D.sc)

function returned:
deriv((y ~ sin(cos(x) * y)), c("x", "y"), func = TRUE)

function with defaulted arguments:
(fx <- deriv(y ~ b0 + b1 * 2^{(-x/th)}, c("b0", "b1", "th"),
 function(b0, b1, th, x = 1:7){}))
fx(2, 3, 4)

Higher derivatives
deriv3(y ~ b0 + b1 * 2^{(-x/th)}, c("b0", "b1", "th"),
 c("b0", "b1", "th", "x"))

Higher derivatives:
DD <- function(expr, name, order = 1) {
 if(order < 1) stop("order must be >= 1")
 if(order == 1) D(expr, name)
 else DD(D(expr, name), name, order - 1)
}
DD(expression(sin(x^2)), "x", 3)
showing the limits of the internal "simplify()":
Not run:
-sin(x^2) * (2 * x) * 2 + ((cos(x^2) * (2 * x) * (2 * x) + sin(x^2) *
2) * (2 * x) + sin(x^2) * (2 * x) * 2)

End(Not run)

```

**Description**

Returns the deviance of a fitted model object.

**Usage**

```
deviance(object, ...)
```

**Arguments**

- |        |                                              |
|--------|----------------------------------------------|
| object | an object for which the deviance is desired. |
| ...    | additional optional argument.                |

**Details**

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

**Value**

The value of the deviance extracted from the object object.

**References**

|-----------------------------|------------------------------------|
| <a href="#">df.residual</a> | <i>Residual Degrees-of-Freedom</i> |
|-----------------------------|------------------------------------|

---

**Description**

Returns the residual degrees-of-freedom extracted from a fitted model object.

**Usage**

```
df.residual(object, ...)
```

**Arguments**

- |        |                                                         |
|--------|---------------------------------------------------------|
| object | an object for which the degrees-of-freedom are desired. |
| ...    | additional optional arguments.                          |

**Details**

This is a generic function which can be used to extract residual degrees-of-freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the df.residual component.

**Value**

The value of the residual degrees-of-freedom extracted from the object *x*.

**See Also**

[deviance](#), [glm](#), [lm](#).

**diffinv**

*Discrete Integration: Inverse of Differencing*

**Description**

Computes the inverse function of the lagged differences function [diff](#).

**Usage**

```
diffinv(x, ...)
Default S3 method:
diffinv(x, lag = 1, differences = 1, xi, ...)
S3 method for class ts
diffinv(x, lag = 1, differences = 1, xi, ...)
```

**Arguments**

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>x</i>           | a numeric vector, matrix, or time series.                                                                             |
| <i>lag</i>         | a scalar lag parameter.                                                                                               |
| <i>differences</i> | an integer representing the order of the difference.                                                                  |
| <i>xi</i>          | a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used. |
| ...                | arguments passed to or from other methods.                                                                            |

**Details**

*diffinv* is a generic function with methods for class "ts" and default for vectors and matrices. Missing values are not handled.

**Value**

A numeric vector, matrix, or time series (the latter for the "ts" method) representing the discrete integral of *x*.

## Description

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

## Usage

```
dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)

as.dist(m, diag = FALSE, upper = FALSE)
Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)

S3 method for class dist
print(x, diag = NULL, upper = NULL,
 digits = getOption("digits"), justify = "none",
 right = TRUE, ...)

S3 method for class dist
as.matrix(x, ...)
```

## Arguments

- x a numeric matrix, data frame or "dist" object.
- method the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
- diag logical value indicating whether the diagonal of the distance matrix should be printed by `print.dist`.
- upper logical value indicating whether the upper triangle of the distance matrix should be printed by `print.dist`.
- p The power of the Minkowski distance.
- m An object with distance information to be converted to a "dist" object. For the default method, a "dist" object, or a matrix (of distances) or an object which can be coerced to such a matrix using `as.matrix()`. (Only the lower triangle of the matrix is used, the rest is ignored).
- digits, justify passed to `format` inside of `print()`.
- right, ... further arguments, passed to other methods.

## Details

Available distance measures are (written for two vectors  $x$  and  $y$ ):

**euclidean:** Usual square distance between the two vectors (2 norm).

**maximum:** Maximum distance between two components of  $x$  and  $y$  (supremum norm)

**manhattan:** Absolute distance between the two vectors (1 norm).

**canberra:**  $\sum_i |x_i - y_i| / |x_i + y_i|$ . Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.

This is intended for non-negative values (e.g. counts): taking the absolute value of the denominator is a 1998 R modification to avoid negative distances.

**binary:** (aka *asymmetric binary*): The vectors are regarded as binary bits, so non-zero elements are ‘on’ and zero elements are ‘off’. The distance is the *proportion* of bits in which only one is on amongst those in which at least one is on.

**minkowski:** The  $p$  norm, the  $p$ th root of the sum of the  $p$ th powers of the differences of the components.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. Further, when Inf values are involved, all pairs of values are excluded when their contribution to the distance gave NaN or NA. If some columns are excluded in calculating a Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is NA.

The “*dist*” method of `as.matrix()` and `as.dist()` can be used for conversion between objects of class “*dist*” and conventional distance matrices.

`as.dist()` is a generic function. Its default method handles objects inheriting from class “*dist*”, or coercible to matrices using `as.matrix()`. Support for classes representing distances (also known as dissimilarities) can be added by providing an `as.matrix()` or, more directly, an `as.dist` method for such a class.

## Value

`dist` returns an object of class “*dist*”.

The lower triangle of the distance matrix stored by columns in a vector, say `do`. If  $n$  is the number of observations, i.e., `n <- attr(do, "Size")`, then for  $i < j \leq n$ , the dissimilarity between (row)  $i$  and  $j$  is  $do[n*(i-1) - i*(i-1)/2 + j-i]$ . The length of the vector is  $n * (n - 1)/2$ , i.e., of order  $n^2$ .

The object has the following attributes (besides “*class*” equal to “*dist*”):

|                                        |                                                                                                                                             |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Size</code>                      | integer, the number of observations in the dataset.                                                                                         |
| <code>Labels</code>                    | optionally, contains the labels, if any, of the observations of the dataset.                                                                |
| <code>Diag</code> , <code>Upper</code> | logicals corresponding to the arguments <code>diag</code> and <code>upper</code> above, specifying how the object should be printed.        |
| <code>call</code>                      | optionally, the <code>call</code> used to create the object.                                                                                |
| <code>method</code>                    | optionally, the distance method used; resulting from <code>dist()</code> , the ( <code>match.arg()</code> ed) <code>method</code> argument. |

[daisy](#) in the **cluster** package with more possibilities in the case of *mixed* (continuous / categorical) variables. [hclust](#).

## Examples

```
require(graphics)

x <- matrix(rnorm(100), nrow = 5)
dist(x)
dist(x, diag = TRUE)
dist(x, upper = TRUE)
m <- as.matrix(dist(x))
d <- as.dist(m)
stopifnot(d == dist(x))

Use correlations between variables "as distance"
dd <- as.dist((1 - cor(USJudgeRatings))/2)
round(1000 * dd) # (prints more nicely)
plot(hclust(dd)) # to see a dendrogram of clustered variables

example of binary and canberra distances.
x <- c(0, 0, 1, 1, 1)
y <- c(1, 0, 1, 1, 0)
dist(rbind(x, y), method = "binary")
answer 0.4 = 2/5
dist(rbind(x, y), method = "canberra")
answer 2 * (6/5)

To find the names
labels(eurodist)

Examples involving "Inf" :
1)
x[6] <- Inf
(m2 <- rbind(x, y))
dist(m2, method = "binary") # warning, answer 0.5 = 2/4
These all give "Inf":
stopifnot(Inf == dist(m2, method = "euclidean"),
 Inf == dist(m2, method = "maximum"),
 Inf == dist(m2, method = "manhattan"))
"Inf" is same as very large number:
x1 <- x; x1[6] <- 1e100
stopifnot(dist(cbind(x, y), method = "canberra") ==
 print(dist(cbind(x1, y), method = "canberra")))

2)
```

```
y[6] <- Inf #-> 6-th pair is excluded
dist(rbind(x, y), method = "binary") # warning; 0.5
dist(rbind(x, y), method = "canberra") # 3
dist(rbind(x, y), method = "maximum") # 1
dist(rbind(x, y), method = "manhattan") # 2.4
```

**Distributions***Distributions in the stats package***Description**

Density, cumulative distribution function, quantile function and random variate generation for many standard probability distributions are available in the **stats** package.

**Details**

The functions for the density/mass function, cumulative distribution function, quantile function and random variate generation are named in the form `dxxx`, `pxxx`, `qxxx` and `rxxx` respectively.

For the beta distribution see [dbeta](#).

For the binomial (including Bernoulli) distribution see [dbinom](#).

For the Cauchy distribution see [dcauchy](#).

For the chi-squared distribution see [dchisq](#).

For the exponential distribution see [dexp](#).

For the F distribution see [df](#).

For the gamma distribution see [dgamma](#).

For the geometric distribution see [dgeom](#). (This is also a special case of the negative binomial.)

For the hypergeometric distribution see [dhyper](#).

For the log-normal distribution see [dlnorm](#).

For the multinomial distribution see [dmultinom](#).

For the negative binomial distribution see [dnbinom](#).

For the normal distribution see [dnorm](#).

For the Poisson distribution see [dpois](#).

For the Student's t distribution see [dt](#).

For the uniform distribution see [dunif](#).

For the Weibull distribution see [dweibull](#).

For less common distributions of test statistics see [pbirthday](#), [dsignrank](#), [ptukey](#) and [dwilcox](#) (and see the ‘See Also’ section of [cor.test](#)).

`dummy.coef`*Extract Coefficients in Original Coding*

---

## Description

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

## Usage

```
dummy.coef(object, ...)

S3 method for class lm
dummy.coef(object, use.na = FALSE, ...)

S3 method for class aovlist
dummy.coef(object, use.na = FALSE, ...)
```

## Arguments

- |        |                                                                                                                                                                          |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | a linear model fit.                                                                                                                                                      |
| use.na | logical flag for coefficients in a singular model. If <code>use.na</code> is true, undetermined coefficients will be missing; if false they will get one possible value. |
| ...    | arguments passed to or from other methods.                                                                                                                               |

## Details

A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for `contr.helmert` or `contr.sum`) will be respected. There will be little point in using `dummy.coef` for `contr.treatment` contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as `poly(x, 2)`. However, it is adequate for its main purpose, `aov` models.

## Value

A list giving for each term the values of the coefficients. For a multistratum `aov` model, such a list for each stratum.

## Warning

This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

options(contrasts = c("contr.helmert", "contr.poly"))
From Venables and Ripley (2002) p.165.
npk.aov <- aov(yield ~ block + N*P*K, npk)
dummy.coef(npk.aov)

npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
dummy.coef(npk.aovE)
```

## ecdf

### *Empirical Cumulative Distribution Function*

## Description

Compute an empirical cumulative distribution function, with several methods for plotting, printing and computing with such an “ecdf” object.

## Usage

```
ecdf(x)

S3 method for class ecdf
plot(x, ..., ylab="Fn(x)", verticals = FALSE,
 col.01line = "gray70", pch = 19)

S3 method for class ecdf
print(x, digits= getOption("digits") - 2, ...)

S3 method for class ecdf
summary(object, ...)
S3 method for class ecdf
quantile(x, ...)
```

## Arguments

|            |                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------|
| x, object  | numeric vector of the observations for ecdf; for the methods, an object inheriting from class “ecdf”.          |
| ...        | arguments to be passed to subsequent methods, e.g., <a href="#">plot.stepfun</a> for the plot method.          |
| ylab       | label for the y-axis.                                                                                          |
| verticals  | see <a href="#">plot.stepfun</a> .                                                                             |
| col.01line | numeric or character specifying the color of the horizontal lines at y = 0 and 1, see <a href="#">colors</a> . |
| pch        | plotting character.                                                                                            |
| digits     | number of significant digits to use, see <a href="#">print</a> .                                               |

## Details

The e.c.d.f. (empirical cumulative distribution function)  $F_n$  is a step function with jumps  $i/n$  at observation values, where  $i$  is the number of tied observations at that value. Missing values are ignored.

For observations  $x = (x_1, x_2, \dots, x_n)$ ,  $F_n$  is the fraction of observations less or equal to  $t$ , i.e.,

$$F_n(t) = \#\{x_i \leq t\} / n = \frac{1}{n} \sum_{i=1}^n \mathbf{1}_{[x_i \leq t]}.$$

The function `plot.ecdf` which implements the [plot](#) method for `ecdf` objects, is implemented via a call to [plot.stepfun](#); see its documentation.

## Value

For `ecdf`, a function of class "ecdf", inheriting from the "[stepfun](#)" class, and hence inheriting a `knots()` method.

For the `summary` method, a summary of the knots of object with a "header" attribute.

The `quantile(obj, ...)` method computes the same quantiles as `quantile(x, ...)` would where `x` is the original sample.

```

**eff.aovlist***Compute Efficiencies of Multistratum Analysis of Variance***Description**

Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

**Usage**

```
eff.aovlist(aovlist)
```

**Arguments**

|         |                                                 |
|---------|-------------------------------------------------|
| aovlist | The result of a call to aov with an Error term. |
|---------|-------------------------------------------------|

**Details**

Fixed-effect terms in an analysis of variance model with multiple strata may be estimable in more than one stratum, in which case there is less than complete information in each. The efficiency for a term is the fraction of the maximum possible precision (inverse variance) obtainable by estimating in just that stratum. Under the assumption of balance, this is the same for all contrasts involving that term.

This function is used to pick strata in which to estimate terms in `model.tables.aovlist` and `se.contrast.aovlist`.

In many cases terms will only occur in one stratum, when all the efficiencies will be one: this is detected and no further calculations are done.

The calculation used requires orthogonal contrasts for each term, and will throw an error if non-orthogonal contrasts (e.g. treatment contrasts or an unbalanced design) are detected.

### Value

A matrix giving for each non-pure-error stratum (row) the efficiencies for each fixed-effect term in the model.

### References

Heiberger, R. M. (1989) *Computation for the Analysis of Designed Experiments*. Wiley.

### See Also

### Examples

```
An example from Yates (1932),
a 2^3 design in 2 blocks replicated 4 times

Block <- gl(8, 4)
A <- factor(c(0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,
 0,1,0,1,0,1,0,1,0,1,0,1))
B <- factor(c(0,0,1,1,0,0,1,1,0,1,0,1,1,0,1,0,0,0,1,1,
 0,0,1,1,0,0,1,1,0,0,1,1))
C <- factor(c(0,1,1,0,1,0,0,1,0,0,1,1,0,0,1,1,0,1,
 1,0,1,0,0,0,1,1,1,1,0,0))
Yield <- c(101, 373, 298, 291, 312, 106, 265, 450, 106, 306, 324, 449,
 272, 89, 407, 338, 87, 324, 279, 471, 323, 128, 423, 334,
 131, 103, 445, 437, 324, 361, 302, 272)
aovdat <- data.frame(Block, A, B, C, Yield)

old <- getOption("contrasts")
options(contrasts = c("contr.helmert", "contr.poly"))
(fit <- aov(Yield ~ A*B*C + Error(Block), data = aovdat))
eff.aovlist(fit)
options(contrasts = old)
```

### Description

Returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a methods for objects inheriting from classes "`lm`" and "`glm`".

**Usage**

```
effects(object, ...)

S3 method for class lm
effects(object, set.sign = FALSE, ...)
```

**Arguments**

- `object` an R object; typically, the result of a model fitting function such as [lm](#).
- `set.sign` logical. If TRUE, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary.
- `...` arguments passed to or from other methods.

**Details**

For a linear model fitted by [lm](#) or [aov](#), the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first  $r$  (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.

**Value**

A (named) numeric vector of the same length as [residuals](#), or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first  $r$  rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the corresponding coefficients will be in a different order if pivoting occurred.

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

[coef](#)

**Examples**

```
y <- c(1:3, 7, 5)
x <- c(1:3, 6:7)
(ee <- effects(lm(y ~ x)))
c(round(ee - effects(lm(y+10 ~ I(x-3.8))), 3))
just the first is different
```

---

|       |                                |
|-------|--------------------------------|
| embed | <i>Embedding a Time Series</i> |
|-------|--------------------------------|

---

## Description

Embeds the time series  $x$  into a low-dimensional Euclidean space.

## Usage

```
embed (x, dimension = 1)
```

## Arguments

|           |                                                |
|-----------|------------------------------------------------|
| $x$       | a numeric vector, matrix, or time series.      |
| dimension | a scalar representing the embedding dimension. |

## Details

Each row of the resulting matrix consists of sequences  $x[t]$ ,  $x[t-1]$ , ...,  $x[t-dimension+1]$ , where  $t$  is the original index of  $x$ . If  $x$  is a matrix, i.e.,  $x$  contains more than one variable, then  $x[t]$  consists of the  $t$ th observation on each variable.

## Value

A matrix containing the embedded time series  $x$ .

## Author(s)

A. Trapletti, B.D. Ripley

## Examples

```
x <- 1:10
embed (x, 3)
```

---

|                    |                                           |
|--------------------|-------------------------------------------|
| expand.model.frame | <i>Add new variables to a model frame</i> |
|--------------------|-------------------------------------------|

---

## Description

Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same na.action and subset arguments are applied and allows, for example,  $x$  to be recovered for a model using  $\sin(x)$  as a predictor.

## Usage

```
expand.model.frame(model, extras,
 envir = environment(formula(model)),
 na.expand = FALSE)
```

## Arguments

|                        |                                                                                       |
|------------------------|---------------------------------------------------------------------------------------|
| <code>model</code>     | a fitted model                                                                        |
| <code>extras</code>    | one-sided formula or vector of character strings describing new variables to be added |
| <code>envir</code>     | an environment to evaluate things in                                                  |
| <code>na.expand</code> | logical; see below                                                                    |

## Details

If `na.expand = FALSE` then NA values in the extra variables will be passed to the `na.action` function used in `model`. This may result in a shorter data frame (with `na.omit`) or an error (with `na.fail`). If `na.expand = TRUE` the returned data frame will have precisely the same rows as `model.frame(model)`, but the columns corresponding to the extra variables may contain NA.

## Value

A data frame.

## See Also

`model.frame`, `predict`

## Examples

```
model <- lm(log(Volume) ~ log(Girth) + log(Height), data = trees)
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x = 1:5, y = rnorm(5), z = c(1,2,NA,4,5))
model <- glm(y ~ x, data = dd, subset = 1:4, na.action = na.omit)
expand.model.frame(model, "z", na.expand = FALSE) # = default
expand.model.frame(model, "z", na.expand = TRUE)
```

## Description

Density, distribution function, quantile function and random generation for the exponential distribution with rate `rate` (i.e., mean  $1/rate$ ).

## Usage

```
dexp(x, rate = 1, log = FALSE)
pexp(q, rate = 1, lower.tail = TRUE, log.p = FALSE)
qexp(p, rate = 1, lower.tail = TRUE, log.p = FALSE)
rexp(n, rate = 1)
```

### Arguments

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                      |
| <code>p</code>          | vector of probabilities.                                                                                  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>rate</code>       | vector of rates.                                                                                          |
| <code>log, log.p</code> | logical; if TRUE, probabilities p are given as log(p).                                                    |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

### Details

If `rate` is not specified, it assumes the default value of 1.

The exponential distribution with rate  $\lambda$  has density

$$f(x) = \lambda e^{-\lambda x}$$

for  $x \geq 0$ .

### Value

`dexp` gives the density, `pexp` gives the distribution function, `qexp` gives the quantile function, and `rexp` generates random deviates.

The length of the result is determined by `n` for `rexp`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

### Note

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is `-pexp(t, r, lower = FALSE, log = TRUE)`.

### Source

`dexp`, `pexp` and `qexp` are all calculated from numerically stable versions of the definitions.

`rexp` uses

Ahrens, J. H. and Dieter, U. (1972). Computer methods for sampling from the exponential and normal distributions. *Communications of the ACM*, **15**, 873–882.

## Examples

```
dexp(1) - exp(-1) #-> 0

a fast way to generate *sorted* U[0,1] random numbers:
rsunif <- function(n) { n1 <- n+1
 cE <- cumsum(rexp(n1)); cE[seq_len(n)]/cE[n1] }
plot(rsunif(1000), ylim=0:1, pch=".")
abline(0,1/(1000+1), col=adjustcolor(1, 0.5))
```

**extractAIC**

*Extract AIC from a Fitted Model*

## Description

Computes the (generalized) Akaike An Information Criterion for a fitted parametric model.

## Usage

```
extractAIC(fit, scale, k = 2, ...)
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>fit</b>   | fitted model, usually the result of a fitter like <a href="#">lm</a> .                                                                                                                                                                                                                             |
| <b>scale</b> | optional numeric specifying the scale parameter of the model, see <b>scale</b> in <a href="#">step</a> . Currently only used in the "lm" method, where <b>scale</b> specifies the estimate of the error variance, and <b>scale</b> = 0 indicates that it is to be estimated by maximum likelihood. |
| <b>k</b>     | numeric specifying the 'weight' of the <i>equivalent degrees of freedom</i> ( $\equiv \text{edf}$ ) part in the AIC formula.                                                                                                                                                                       |
| <b>...</b>   | further arguments (currently unused in base R).                                                                                                                                                                                                                                                    |

## Details

This is a generic function, with methods in base R for classes "aov", "glm" and "lm" as well as for "negbin" (package **MASS**) and "coxph" and "survreg" (package **survival**).

The criterion used is

$$AIC = -2 \log L + k \times \text{edf},$$

where  $L$  is the likelihood and  $\text{edf}$  the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of **fit**.

For linear models with unknown scale (i.e., for [lm](#) and [aov](#)),  $-2 \log L$  is computed from the *deviance* and uses a different additive constant to [logLik](#) and hence [AIC](#). If  $RSS$  denotes the (weighted) residual sum of squares then **extractAIC** uses for  $-2 \log L$  the formulae  $RSS/s - n$  (corresponding to Mallows'  $C_p$ ) in the case of known scale  $s$  and  $n \log(RSS/n)$  for unknown scale. [AIC](#) only handles unknown scale and uses the formula  $n \log(RSS/n) + n + n \log 2\pi - \sum \log w$  where  $w$  are the weights. Further AIC counts the scale estimation as a parameter in the edf and **extractAIC** does not.

For [glm](#) fits the family's [aic\(\)](#) function is used to compute the AIC: see the note under [logLik](#) about the assumptions this makes.

`k = 2` corresponds to the traditional AIC, using `k = log(n)` provides the BIC (Bayesian IC) instead.

Note that the methods for this function may differ in their assumptions from those of methods for `AIC` (usually *via* a method for `logLik`). We have already mentioned the case of "`lm`" models with estimated scale, and there are similar issues in the "`glm`" and "`negbin`" methods where the dispersion parameter may or may not be taken as 'free'. This is immaterial as `extractAIC` is only used to compare models of the same class (where only differences in AIC values are considered).

### Value

A numeric vector of length 2, with first and second elements giving

- |                  |                                                                             |
|------------------|-----------------------------------------------------------------------------|
| <code>edf</code> | the ‘equivalent degrees of freedom’ for the fitted model <code>fit</code> . |
| <code>AIC</code> | the (generalized) Akaike Information Criterion for <code>fit</code> .       |

### Note

This function is used in `add1`, `drop1` and `step` and the similar functions in package **MASS** from which it was adopted.

### Examples

```
utils::example(glm)
extractAIC(glm.D93) #>> 5 15.129
```

### Description

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

### Usage

```
factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
 subset, na.action, start = NULL,
 scores = c("none", "regression", "Bartlett"),
 rotation = "varimax", control = NULL, ...)
```

## Arguments

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>         | A formula or a numeric matrix or an object that can be coerced to a numeric matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>factors</b>   | The number of factors to be fitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>data</b>      | An optional data frame (or similar: see <a href="#">model.frame</a> ), used only if <b>x</b> is a formula. By default the variables are taken from <a href="#">environment(formula)</a> .                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>covmat</b>    | A covariance matrix, or a covariance list as returned by <a href="#">cov.wt</a> . Of course, correlation matrices are covariance matrices.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>n.obs</b>     | The number of observations, used if <b>covmat</b> is a covariance matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>subset</b>    | A specification of the cases to be used, if <b>x</b> is used as a matrix or formula.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>na.action</b> | The <b>na.action</b> to be used if <b>x</b> is used as a formula.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>start</b>     | NULL or a matrix of starting values, each column giving an initial set of uniquenesses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>scores</b>    | Type of scores to produce, if any. The default is <b>none</b> , "regression" gives Thompson's scores, "Bartlett" given Bartlett's weighted least-squares scores. Partial matching allows these names to be abbreviated.                                                                                                                                                                                                                                                                                                                                                        |
| <b>rotation</b>  | character. "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component <b>loadings</b> giving the rotated loadings, or just the rotated loadings.                                                                                                                                                                                                                                                                                                                    |
| <b>control</b>   | A list of control values,<br><b>nstart</b> The number of starting values to be tried if <b>start = NULL</b> . Default 1.<br><b>trace</b> logical. Output tracing information? Default FALSE.<br><b>lower</b> The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005.<br><b>opt</b> A list of control values to be passed to <a href="#">optim</a> 's control argument.<br><b>rotate</b> a list of additional arguments for the rotation function.<br>... Components of <b>control</b> can also be supplied as named arguments to <b>factanal</b> . |

## Details

The factor analysis model is

$$x = \Lambda f + e$$

for a  $p$ -element row-vector  $x$ , a  $p \times k$  matrix  $\Lambda$  of *loadings*, a  $k$ -element vector  $f$  of *scores* and a  $p$ -element vector  $e$  of errors. None of the components other than  $x$  is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances  $\Psi$ , the *uniquenesses*. It is also common to scale the observed variables to unit variance, and done in this function.

Thus factor analysis is in essence a model for the correlation matrix of  $x$ ,

$$\Sigma = \Lambda' \Lambda + \Psi$$

There is still some indeterminacy in the model for it is unchanged if  $\Lambda$  is replaced by  $G\Lambda$  for any orthogonal matrix  $G$ . Such matrices  $G$  are known as *rotations* (although the term is applied also to non-orthogonal invertible matrices).

If **covmat** is supplied it is used. Otherwise **x** is used if it is a matrix, or a formula **x** is used with **data** to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for

the formula to have a response, and all the variables must be numeric.) Once a covariance matrix is found or calculated from  $x$ , it is converted to a correlation matrix for analysis. The correlation matrix is returned as component **correlation** of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in **start** are tried in turn and the best fit obtained is used. If **start** = NULL then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then **control\$nstart** - 1 other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in [0, 1], but near-zero values are problematical, and the optimization is done with a lower bound of **control\$lower**, default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8). Both are estimates of the unobserved scores  $f$ . Thomson's method regresses (in the population) the unknown  $f$  on  $x$  to yield

$$\hat{f} = \Lambda' \Sigma^{-1} x$$

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett's method minimizes the sum of squares of standardized errors over the choice of  $f$ , given (the fitted)  $\Lambda$ .

If  $x$  is a formula then the standard NA-handling is applied to the scores (if requested): see [napredict](#).

The **print** method (documented under [loadings](#)) follows the factor analysis convention of drawing attention to the patterns of the results, so the default precision is three decimal places, and small loadings are suppressed.

## Value

An object of class "factanal" with components

|                        |                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>loadings</b>        | A matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive. This is of class "loadings": see <a href="#">loadings</a> for its <b>print</b> method. |
| <b>uniquenesses</b>    | The uniquenesses computed.                                                                                                                                                                                                                                                               |
| <b>correlation</b>     | The correlation matrix used.                                                                                                                                                                                                                                                             |
| <b>criteria</b>        | The results of the optimization: the value of the negative log-likelihood and information on the iterations used.                                                                                                                                                                        |
| <b>factors</b>         | The argument <b>factors</b> .                                                                                                                                                                                                                                                            |
| <b>dof</b>             | The number of degrees of freedom of the factor analysis model.                                                                                                                                                                                                                           |
| <b>method</b>          | The method: always "mle".                                                                                                                                                                                                                                                                |
| <b>rotmat</b>          | The rotation matrix if relevant.                                                                                                                                                                                                                                                         |
| <b>scores</b>          | If requested, a matrix of scores. <a href="#">napredict</a> is applied to handle the treatment of values omitted by the <b>na.action</b> .                                                                                                                                               |
| <b>n.obs</b>           | The number of observations if available, or NA.                                                                                                                                                                                                                                          |
| <b>call</b>            | The matched call.                                                                                                                                                                                                                                                                        |
| <b>na.action</b>       | If relevant.                                                                                                                                                                                                                                                                             |
| <b>STATISTIC, PVAL</b> | The significance-test statistic and P value, if it can be computed.                                                                                                                                                                                                                      |

### Note

There are so many variations on factor analysis that it is hard to compare output from different programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other examples we compared had less good fits than produced by this function. In particular, solutions which are ‘Heywood cases’ (with one or more uniquenesses essentially zero) are much more common than most texts and some other programs would lead one to believe.

### Examples

```
A little demonstration, v2 is just v1 with noise,
and same for v4 vs. v3 and v6 vs. v5
Last four cases are there to add noise
and introduce a positive manifold (g factor)
v1 <- c(1,1,1,1,1,1,1,1,1,3,3,3,3,4,5,6)
v2 <- c(1,2,1,1,1,1,2,1,2,1,3,4,3,3,3,4,6,5)
v3 <- c(3,3,3,3,1,1,1,1,1,1,1,1,1,5,4,6)
v4 <- c(3,3,4,3,3,1,1,2,1,1,1,2,1,1,5,6,4)
v5 <- c(1,1,1,1,1,3,3,3,3,1,1,1,1,1,6,4,5)
v6 <- c(1,1,1,2,1,3,3,3,4,3,1,1,2,1,6,5,4)
m1 <- cbind(v1,v2,v3,v4,v5,v6)
cor(m1)
factanal(m1, factors = 3) # varimax is the default
factanal(m1, factors = 3, rotation = "promax")
The following shows the g factor as PC1
prcomp(m1) # signs may depend on platform

formula interface
factanal(~v1+v2+v3+v4+v5+v6, factors = 3,
 scores = "Bartlett")$scores

a realistic example from Bartholomew (1987, pp. 61-65)

|                           |                                                                        |
|---------------------------|------------------------------------------------------------------------|
| <code>factor.scope</code> | <i>Compute Allowed Changes in Adding to or Dropping from a Formula</i> |
|---------------------------|------------------------------------------------------------------------|

---

## Description

`add.scope` and `drop.scope` compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

## Usage

```
add.scope(terms1, terms2)

drop.scope(terms1, terms2)

factor.scope(factor, scope)
```

## Arguments

|                     |                                                                                                                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>terms1</code> | the terms or formula for the base model.                                                                                                                                                                                                                  |
| <code>terms2</code> | the terms or formula for the upper ( <code>add.scope</code> ) or lower ( <code>drop.scope</code> ) scope.<br>If missing for <code>drop.scope</code> it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped. |
| <code>factor</code> | the "factor" attribute of the terms of the base object.                                                                                                                                                                                                   |
| <code>scope</code>  | a list with one or both components <code>drop</code> and <code>add</code> giving the "factor" attribute of the lower and upper scopes respectively.                                                                                                       |

## Details

`factor.scope` is not intended to be called directly by users.

## Value

For `add.scope` and `drop.scope` a character vector of terms labels. For `factor.scope`, a list with components `drop` and `add`, character vectors of terms labels.

## See Also

[add1](#), [drop1](#), [aov](#), [lm](#)

## Examples

```
add.scope(~ a + b + c + a:b, ~ (a + b + c)^3)
[1] "a:c" "b:c"
drop.scope(~ a + b + c + a:b)
[1] "c" "a:b"
```

**family***Family Objects for Models*

---

**Description**

Family objects provide a convenient way to specify the details of the models used by functions such as [glm](#). See the documentation for [glm](#) for the details on how such model fitting takes place.

**Usage**

```
family(object, ...)

binomial(link = "logit")
gaussian(link = "identity")
Gamma(link = "inverse")
inverse.gaussian(link = "1/mu^2")
poisson(link = "log")
quasi(link = "identity", variance = "constant")
quasibinomial(link = "logit")
quasipoisson(link = "log")
```

**Arguments**

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>link</b>     | a specification for the model link function. This can be a name/expression, a literal character string, a length-one character vector or an object of class " <a href="#">link-glm</a> " (such as generated by <a href="#">make.link</a> ) provided it is not specified <i>via</i> one of the standard names given next.<br>The gaussian family accepts the links (as names) identity, log and inverse; the binomial family the links logit, probit, cauchit, (corresponding to logistic, normal and Cauchy CDFs respectively) log and cloglog (complementary log-log); the Gamma family the links inverse, identity and log; the poisson family the links log, identity, and sqrt and the inverse.gaussian family the links 1/mu^2, inverse, identity and log.<br>The quasi family accepts the links logit, probit, cloglog, identity, inverse, log, 1/mu^2 and sqrt, and the function <a href="#">power</a> can be used to create a power link function. |
| <b>variance</b> | for all families other than quasi, the variance function is determined by the family. The quasi family will accept the literal character string (or unquoted as a name/expression) specifications "constant", "mu(1-mu)", "mu", "mu^2" and "mu^3", a length-one character vector taking one of those values, or a list containing components varfun, validmu, dev.resids, initialize and name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>object</b>   | the function <b>family</b> accesses the <b>family</b> objects which are stored within objects created by modelling functions (e.g., <a href="#">glm</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>...</b>      | further arguments passed to methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Details**

**family** is a generic function with methods for classes "[glm](#)" and "[lm](#)" (the latter returning [gaussian\(\)](#)).

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can model over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that `glm` does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi- variants.

### Value

An object of class "family" (which has a concise print method). This is a list with elements

|                         |                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>family</code>     | character: the family name.                                                                                                                                                                                                                                                                                                              |
| <code>link</code>       | character: the link name.                                                                                                                                                                                                                                                                                                                |
| <code>linkfun</code>    | function: the link.                                                                                                                                                                                                                                                                                                                      |
| <code>linkinv</code>    | function: the inverse of the link function.                                                                                                                                                                                                                                                                                              |
| <code>variance</code>   | function: the variance as a function of the mean.                                                                                                                                                                                                                                                                                        |
| <code>dev.resids</code> | function giving the deviance residuals as a function of ( <code>y</code> , <code>mu</code> , <code>wt</code> ).                                                                                                                                                                                                                          |
| <code>aic</code>        | function giving the AIC value if appropriate (but NA for the quasi- families). See <a href="#">logLik</a> for the assumptions made about the dispersion parameter.                                                                                                                                                                       |
| <code>mu.eta</code>     | function: derivative $d\mu/d\eta$ .                                                                                                                                                                                                                                                                                                      |
| <code>initialize</code> | expression. This needs to set up whatever data objects are needed for the family as well as <code>n</code> (needed for AIC in the binomial family) and <code>mustart</code> (see <a href="#">glm</a> ).                                                                                                                                  |
| <code>valid.mu</code>   | logical function. Returns TRUE if a mean vector <code>mu</code> is within the domain of <code>variance</code> .                                                                                                                                                                                                                          |
| <code>valid.eta</code>  | logical function. Returns TRUE if a linear predictor <code>eta</code> is within the domain of <code>linkinv</code> .                                                                                                                                                                                                                     |
| <code>simulate</code>   | (optional) function <code>simulate(object, nsim)</code> to be called by the "lm" method of <a href="#">simulate</a> . It will normally return a matrix with <code>nsim</code> columns and one row for each fitted value, but it can also return a list of length <code>nsim</code> . Clearly this will be missing for 'quasi-' families. |

### Note

The `link` and `variance` arguments have rather awkward semantics for back-compatibility. The recommended way is to supply them as quoted character strings, but they can also be supplied unquoted (as names or expressions). In addition, they can also be supplied as a length-one character vector giving the name of one of the options, or as a list (for `link`, of class "link-glm"). The restrictions apply only to links given as names: when given as a character string all the links known to [make.link](#) are accepted.

This is potentially ambiguous: supplying `link = logit` could mean the unquoted name of a link or the value of object `logit`. It is interpreted if possible as the name of an allowed link, then as an object. (You can force the interpretation to always be the value of an object via `logit[1]`.)

### Author(s)

The design was inspired by S functions of the same names described in Hastie & Pregibon (1992) (except quasibinomial and quasipoisson).

## Examples

```
require(utils) # for str

nf <- gaussian() # Normal family
nf
str(nf)

gf <- Gamma()
gf
str(gf)
gf$linkinv
gf$variance # - == (.)^2

quasipoisson. compare with example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
d.AD <- data.frame(treatment, outcome, counts)
glm.qD93 <- glm(counts ~ outcome + treatment, family = quasipoisson())

glm.qD93
anova(glm.qD93, test = "F")
summary(glm.qD93)
for Poisson results use
anova(glm.qD93, dispersion = 1, test = "Chisq")
summary(glm.qD93, dispersion = 1)

Example of user-specified link, a logit model for p^days
See Shaffer, T. 2004. Auk 121(2): 526-540.
logexp <- function(days = 1)
{
 linkfun <- function(mu) qlogis(mu^(1/days))
 linkinv <- function(eta) plogis(eta)^days
 mu.eta <- function(eta) days * plogis(eta)^(days-1) * binomial()$mu_eta
 valideta <- function(eta) TRUE
 link <- paste0("logexp(", days, ")")
 structure(list(linkfun = linkfun, linkinv = linkinv,
```

```

 mu.eta = mu.eta, valideta = valideta, name = link),
 class = "link-glm")
}
binomial(logexp(3))
in practice this would be used with a vector of days, in
which case use an offset of 0 in the corresponding formula
to get the null deviance right.

Binomial with identity link: often not a good idea.
Not run: binomial(link = make.link("identity"))

tests of quasi
x <- rnorm(100)
y <- rpois(100, exp(1+x))
glm(y ~ x, family = quasi(variance = "mu", link = "log"))
which is the same as
glm(y ~ x, family = poisson)
glm(y ~ x, family = quasi(variance = "mu^2", link = "log"))
Not run: glm(y ~ x, family = quasi(variance = "mu^3", link = "log")) # fails
y <- rbinom(100, 1, plogis(x))
needs to set a starting value for the next fit
glm(y ~ x, family = quasi(variance = "mu(1-mu)", link = "logit"), start = c(0,1))

```

## Description

Density, distribution function, quantile function and random generation for the F distribution with df1 and df2 degrees of freedom (and optional non-centrality parameter ncp).

## Usage

```

df(x, df1, df2, ncp, log = FALSE)
pf(q, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
qf(p, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
rf(n, df1, df2, ncp)

```

## Arguments

|            |                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------|
| x, q       | vector of quantiles.                                                                                      |
| p          | vector of probabilities.                                                                                  |
| n          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| df1, df2   | degrees of freedom. <code>Inf</code> is allowed.                                                          |
| ncp        | non-centrality parameter. If omitted the central F is assumed.                                            |
| log, log.p | logical; if <code>TRUE</code> , probabilities p are given as <code>log(p)</code> .                        |
| lower.tail | logical; if <code>TRUE</code> (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .        |

## Details

The F distribution with  $\text{df1} = n_1$  and  $\text{df2} = n_2$  degrees of freedom has density

$$f(x) = \frac{\Gamma(n_1/2 + n_2/2)}{\Gamma(n_1/2)\Gamma(n_2/2)} \left(\frac{n_1}{n_2}\right)^{n_1/2} x^{n_1/2-1} \left(1 + \frac{n_1 x}{n_2}\right)^{-(n_1+n_2)/2}$$

for  $x > 0$ .

It is the distribution of the ratio of the mean squares of  $n_1$  and  $n_2$  independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom. Since the ratio of a normal and the root mean-square of  $m$  independent normals has a Student's  $t_m$  distribution, the square of a  $t_m$  variate has a F distribution on 1 and  $m$  degrees of freedom.

The non-central F distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and  $\text{ncp}$  is the sum of squares of the means. See [Chisquare](#) for further details on non-central distributions.

## Value

`df` gives the density, `pf` gives the distribution function `qf` gives the quantile function, and `rf` generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rf`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

## Note

Supplying `ncp = 0` uses the algorithm for the non-central distribution, which is not the same algorithm used if `ncp` is omitted. This is to give consistent behaviour in extreme cases with values of `ncp` very near zero.

The code for non-zero `ncp` is principally intended to be used for moderate values of `ncp`: it will not be highly accurate, especially in the tails, for large values.

## Source

For the central case of `df`, computed via a binomial probability, code contributed by Catherine Loader (see [dbinom](#)); for the non-central case computed via [dbeta](#), code contributed by Peter Ruckdeschel.

For `pf`, via [pbeta](#) (or for large `df2`, via [pchisq](#)).

For `qf`, via [qchisq](#) for large `df2`, else via [qbeta](#).

## Examples

```
Equivalence of pt(.,nu) with pf(.^2, 1,nu):
x <- seq(0.001, 5, len = 100)
nu <- 4
stopifnot(all.equal(2*pt(x,nu) - 1, pf(x^2, 1,nu)),
 ## upper tails:
 all.equal(2*pt(x, nu, lower=FALSE),
 pf(x^2, 1,nu, lower=FALSE)))

the density of the square of a t_m is 2*dt(x, m)/(2*x)
check this is the same as the density of F_{1,m}
all.equal(df(x^2, 1, 5), dt(x, 5)/x)

Identity: qf(2*p - 1, 1, df) == qt(p, df)^2) for p >= 1/2
p <- seq(1/2, .99, length = 50); df <- 10
rel.err <- function(x, y) ifelse(x == y, 0, abs(x-y)/mean(abs(c(x,y))))
quantile(rel.err(qf(2*p - 1, df1 = 1, df2 = df), qt(p, df)^2), .90) # ~ 7e-9
```

## fft

### *Fast Discrete Fourier Transform*

## Description

Performs the Fast Fourier Transform of an array.

## Usage

```
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
```

## Arguments

- |         |                                                                                                                                                                    |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| z       | a real or complex array containing the values to be transformed.                                                                                                   |
| inverse | if TRUE, the unnormalized inverse transform is computed (the inverse has a + in the exponent of $e$ , but here, we do <i>not</i> divide by $1/\text{length}(x)$ ). |

## Value

When z is a vector, the value computed and returned by `fft` is the unnormalized univariate Fourier transform of the sequence of values in z.

When z contains an array, `fft` computes and returns the multivariate (spatial) transform. If `inverse` is TRUE, the (unnormalized) inverse Fourier transform is returned, i.e., if `y <- fft(z)`, then `z` is `fft(y, inverse = TRUE) / length(y)`.

By contrast, `mvfft` takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.

The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

## Source

Uses C translation of Fortran code in Singleton (1979).

```
x <- 1:4
fft(x)
fft(fft(x), inverse = TRUE)/length(x)
```

filter

*Linear Filtering on a Time Series*

## Description

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

## Usage

```
filter(x, filter, method = c("convolution", "recursive"),
 sides = 2, circular = FALSE, init)
```

## Arguments

|          |                                                                                                                                                                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | a univariate or multivariate time series.                                                                                                                                                                                                                             |
| filter   | a vector of filter coefficients in reverse time order (as for AR or MA coefficients).                                                                                                                                                                                 |
| method   | Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used: if "recursive" an autoregression is used.                                                                                                                    |
| sides    | for convolution filters only. If sides = 1 the filter coefficients are for past values only; if sides = 2 they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward. |
| circular | for convolution filters only. If TRUE, wrap the filter around the ends of the series, otherwise assume external values are missing (NA).                                                                                                                              |
| init     | for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.                                                                                                      |

## Details

Missing values are allowed in `x` but not in `filter` (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

$$y_i = x_i + f_1 y_{i-1} + \cdots + f_p y_{i-p}$$

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

$$y_i = f_1 x_{i+o} + \cdots + f_p x_{i+o-(p-1)}$$

where `o` is the offset: see `sides` for how it is determined.

## Value

A time series object.

## Note

`convolve(, type = "filter")` uses the FFT for computations and so *may* be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. `filter` is faster for a filter of length 100 on a series of length 1000, for example.

## See Also

[convolve](#), [arima.sim](#)

## Examples

```
x <- 1:100
filter(x, rep(1, 3))
filter(x, rep(1, 3), sides = 1)
filter(x, rep(1, 3), sides = 1, circular = TRUE)

filter(presidents, rep(1, 3))
```

`fisher.test`

*Fisher's Exact Test for Count Data*

## Description

Performs Fisher's exact test for testing the null of independence of rows and columns in a contingency table with fixed marginals.

## Usage

```
fisher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
 control = list(), or = 1, alternative = "two.sided",
 conf.int = TRUE, conf.level = 0.95,
 simulate.p.value = FALSE, B = 2000)
```

### Arguments

|                  |                                                                                                                                                                                                                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                | either a two-dimensional contingency table in matrix form, or a factor object.                                                                                                                                                                                                                                                       |
| y                | a factor object; ignored if x is a matrix.                                                                                                                                                                                                                                                                                           |
| workspace        | an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than $2 \times 2$ tables.                                                                                                                                                            |
| hybrid           | a logical. Only used for larger than $2 \times 2$ tables, in which cases it indicates whether the exact probabilities (default) or a hybrid approximation thereof should be computed. See ‘Details’.                                                                                                                                 |
| control          | a list with named components for low level algorithm control. At present the only one used is “mult”, a positive integer $\geq 2$ with default 30 used only for larger than $2 \times 2$ tables. This says how many times as much space should be allocated to paths as to keys: see file ‘fexact.c’ in the sources of this package. |
| or               | the hypothesized odds ratio. Only used in the $2 \times 2$ case.                                                                                                                                                                                                                                                                     |
| alternative      | indicates the alternative hypothesis and must be one of “two.sided”, “greater” or “less”. You can specify just the initial letter. Only used in the $2 \times 2$ case.                                                                                                                                                               |
| conf.int         | logical indicating if a confidence interval for the odds ratio in a $2 \times 2$ table should be computed (and returned).                                                                                                                                                                                                            |
| conf.level       | confidence level for the returned confidence interval. Only used in the $2 \times 2$ case and if conf.int = TRUE.                                                                                                                                                                                                                    |
| simulate.p.value | a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than $2 \times 2$ tables.                                                                                                                                                                                                                      |
| B                | an integer specifying the number of replicates used in the Monte Carlo test.                                                                                                                                                                                                                                                         |

### Details

If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

For  $2 \times 2$  cases, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from <http://www.netlib.org/toms/643>. Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than  $2^{31} - 1$ .)

For  $2 \times 2$  tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. ‘Exact’ inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so alternative = “greater” is a test of the odds ratio being bigger than or.

Two-sided tests are based on the probabilities of the tables, and take as ‘more extreme’ all tables with probabilities less than or equal to that of the observed table, the p-value being the sum of such probabilities.

For larger than  $2 \times 2$  tables and `hybrid = TRUE`, asymptotic chi-squared probabilities are only used if the ‘Cochran conditions’ are satisfied, that is if no cell has count zero, and more than 80% of the cells have counts at least 5: otherwise the exact calculation is used.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.)

### Value

A list with class "htest" containing the following components:

|                          |                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>p.value</code>     | the p-value of the test.                                                                                                                                                                                    |
| <code>conf.int</code>    | a confidence interval for the odds ratio. Only present in the $2 \times 2$ case and if argument <code>conf.int = TRUE</code> .                                                                              |
| <code>estimate</code>    | an estimate of the odds ratio. Note that the <i>conditional</i> Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the $2 \times 2$ case. |
| <code>null.value</code>  | the odds ratio under the null, or. Only present in the $2 \times 2$ case.                                                                                                                                   |
| <code>alternative</code> | a character string describing the alternative hypothesis.                                                                                                                                                   |
| <code>method</code>      | the character string "Fisher's Exact Test for Count Data".                                                                                                                                                  |
| <code>data.name</code>   | a character string giving the names of the data.                                                                                                                                                            |

## Examples

```

Agresti (1990, p. 61f; 2002, p. 91) Fishers Tea Drinker
A British woman claimed to be able to distinguish whether milk or
tea was added to the cup first. To test, she was given 8 cups of
tea, in four of which milk was added first. The null hypothesis
is that there is no association between the true order of pouring
and the womans guess, the alternative that there is a positive
association (that the odds ratio is greater than 1).
TeaTasting <-
matrix(c(3, 1, 1, 3),
 nrow = 2,
 dimnames = list(Guess = c("Milk", "Tea"),
 Truth = c("Milk", "Tea"))))
fisher.test(TeaTasting, alternative = "greater")
=> p = 0.2429, association could not be established

Fisher (1962, 1970), Criminal convictions of like-sex twins
Convictions <-
matrix(c(2, 10, 15, 3),
 nrow = 2,
 dimnames =
list(c("Dizygotic", "Monozygotic"),
 c("Convicted", "Not convicted")))
Convictions
fisher.test(Convictions, alternative = "less")
fisher.test(Convictions, conf.int = FALSE)
fisher.test(Convictions, conf.level = 0.95)$conf.int
fisher.test(Convictions, conf.level = 0.99)$conf.int

A r x c table Agresti (2002, p. 57) Job Satisfaction
Job <- matrix(c(1,2,1,0, 3,3,6,1, 10,10,14,9, 6,7,12,11), 4, 4,
dimnames = list(income = c("< 15k", "15-25k", "25-40k", "> 40k"),
satisfaction = c("VeryD", "LittleD", "ModerateS", "VeryS")))
fisher.test(Job)
fisher.test(Job, simulate.p.value = TRUE, B = 1e5)

```

fitted

*Extract Model Fitted Values*

## Description

`fitted` is a generic function which extracts fitted values from objects returned by modeling functions. `fitted.values` is an alias for it.

All object classes which are returned by model fitting functions should provide a `fitted` method. (Note that the generic is `fitted` and not `fitted.values`.)

Methods can make use of `napredict` methods to compensate for the omission of missing values. The default and `nls` methods do.

## Usage

```

fitted(object, ...)
fitted.values(object, ...)

```

**Arguments**

- object            an object for which the extraction of model fitted values is meaningful.  
...                other arguments.

**Value**

Fitted values extracted from the object object.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

[coefficients](#), [glm](#), [lm](#), [residuals](#).

---

fivenum

*Tukey Five-Number Summaries*

---

**Description**

Returns Tukey's five number summary (minimum, lower-hinge, median, upper-hinge, maximum) for the input data.

**Usage**

`fivenum(x, na.rm = TRUE)`

**Arguments**

- x                numeric, maybe including [NAs](#) and [±Infs](#).  
na.rm            logical; if TRUE, all [NA](#) and [NaNs](#) are dropped, before the statistics are computed.

**Value**

A numeric vector of length 5 containing the summary information. See [boxplot.stats](#) for more details.

**See Also**

[IQR](#), [boxplot.stats](#), [median](#), [quantile](#), [range](#).

**Examples**

```
fivenum(c(rnorm(100), -1:1/0))
```

**fligner.test***Fligner-Killeen Test of Homogeneity of Variances***Description**

Performs a Fligner-Killeen (median) test of the null that the variances in each of the groups (samples) are the same.

**Usage**

```
fligner.test(x, ...)

Default S3 method:
fligner.test(x, g, ...)

S3 method for class formula
fligner.test(formula, data, subset, na.action, ...)
```

**Arguments**

- x** a numeric vector of data values, or a list of numeric data vectors.
- g** a vector or factor object giving the group for the corresponding elements of **x**. Ignored if **x** is a list.
- formula** a formula of the form **lhs ~ rhs** where **lhs** gives the data values and **rhs** the corresponding groups.
- data** an optional matrix or data frame (or similar: see [model.frame](#)) containing the variables in the formula **formula**. By default the variables are taken from **environment(formula)**.
- subset** an optional vector specifying a subset of observations to be used.
- na.action** a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- ...** further arguments to be passed to or from methods.

**Details**

If **x** is a list, its elements are taken as the samples to be compared for homogeneity of variances, and hence have to be numeric data vectors. In this case, **g** is ignored, and one can simply use `fligner.test(x)` to perform the test. If the samples are not yet contained in a list, use `fligner.test(list(x, ...))`.

Otherwise, **x** must be a numeric data vector, and **g** must be a vector or factor object of the same length as **x** giving the group for the corresponding elements of **x**.

The Fligner-Killeen (median) test has been determined in a simulation study as one of the many tests for homogeneity of variances which is most robust against departures from normality, see Conover, Johnson & Johnson (1981). It is a  $k$ -sample simple linear rank which uses the ranks of the absolute values of the centered samples and weights  $a(i) = \text{qnorm}((1+i/(n+1))/2)$ . The version implemented here uses median centering in each of the samples (F-K:med  $X^2$  in the reference).

**Value**

A list of class "htest" containing the following components:

|                        |                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------|
| <code>statistic</code> | the Fligner-Killeen:med $X^2$ test statistic.                                             |
| <code>parameter</code> | the degrees of freedom of the approximate chi-squared distribution of the test statistic. |
| <code>p.value</code>   | the p-value of the test.                                                                  |
| <code>method</code>    | the character string "Fligner-Killeen test of homogeneity of variances".                  |
| <code>data.name</code> | a character string giving the names of the data.                                          |

**References**

William J. Conover, Mark E. Johnson and Myrle M. Johnson (1981). A comparative study of tests for homogeneity of variances, with applications to the outer continental shelf bidding data. *Technometrics* **23**, 351–361.

**See Also**

`ansari.test` and `mood.test` for rank-based two-sample test for a difference in scale parameters; `var.test` and `bartlett.test` for parametric tests for the homogeneity of variances.

**Examples**

```
require(graphics)

plot(count ~ spray, data = InsectSprays)
fligner.test(InsectSprays$count, InsectSprays$spray)
fligner.test(count ~ spray, data = InsectSprays)
Compare this to bartlett.test()
```

**Description**

The generic function `formula` and its specific methods provide a way of extracting formulae which have been included in other objects.

`as.formula` is almost identical, additionally preserving attributes when object already inherits from "formula".

**Usage**

```
formula(x, ...)
as.formula(object, env = parent.frame())

S3 method for class formula
print(x, showEnv = !identical(e, .GlobalEnv), ...)
```

## Arguments

|                        |                                                                         |
|------------------------|-------------------------------------------------------------------------|
| <code>x, object</code> | R object.                                                               |
| <code>...</code>       | further arguments passed to or from other methods.                      |
| <code>env</code>       | the environment to associate with the result, if not already a formula. |
| <code>showEnv</code>   | logical indicating if the environment should be printed as well.        |

## Details

The models fit by, e.g., the `lm` and `glm` functions are specified in a compact symbolic form. The `~` operator is basic in the formation of such models. An expression of the form `y ~ model` is interpreted as a specification that the response `y` is modelled by a linear predictor specified symbolically by `model`. Such a model consists of a series of terms separated by `+` operators. The terms themselves consist of variable and factor names separated by `:` operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.

In addition to `+` and `:`, a number of other operators are useful in model formulae. The `*` operator denotes factor crossing: `a*b` interpreted as `a+b+a:b`. The `^` operator indicates crossing to the specified degree. For example `(a+b+c)^2` is identical to `(a+b+c)*(a+b+c)` which in turn expands to a formula containing the main effects for `a`, `b` and `c` together with their second-order interactions. The `%in%` operator indicates that the terms on its left are nested within those on the right. For example `a + b %in% a` expands to the formula `a + a:b`. The `-` operator removes the specified terms, so that `(a+b+c)^2 - a:b` is identical to `a + b + c + b:c + a:c`. It can also be used to remove the intercept term: when fitting a linear model `y ~ x - 1` specifies a line through the origin. A model with no intercept can be also specified as `y ~ x + 0` or `y ~ 0 + x`.

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula `log(y) ~ a + log(x)` is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.

To avoid this confusion, the function `I()` can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula `y ~ a + I(b+c)`, the term `b+c` is to be interpreted as the sum of `b` and `c`.

Variable names can be quoted by backticks like `this` in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

Most model-fitting functions accept formulae with right-hand-side including the function `offset` to indicate terms with a fixed coefficient of one. Some functions accept other ‘specials’ such as `strata` or `cluster` (see the `specials` argument of `terms.formula`).

There are two special interpretations of `.` in a formula. The usual one is in the context of a data argument of model fitting functions and means ‘all columns not otherwise in the formula’: see `terms.formula`. In the context of `update.formula`, `only`, it means ‘what was previously in this part of the formula’.

When `formula` is called on a fitted model object, either a specific method is used (such as that for class “`nls`”) or the default method. The default first looks for a “`formula`” component of the object (and evaluates it), then a “`terms`” component, then a `formula` parameter of the call (and evaluates its value) and finally a “`formula`” attribute.

There is a `formula` method for data frames. If there is only one column this forms the RHS with an empty LHS. For more columns, the first column is the LHS of the formula and the remaining columns separated by `+` form the RHS.

### Value

All the functions above produce an object of class "formula" which contains a symbolic model formula.

### Environments

A formula object has an associated environment, and this environment (rather than the parent environment) is used by `model.frame` to evaluate variables that are not found in the supplied data argument.

Formulas created with the `~` operator use the environment in which they were created. Formulas created with `as.formula` will use the `env` argument for their environment.

### See Also

`I`, `offset`.

For formula manipulation: `terms`, and `all.vars`; for typical use: `lm`, `glm`, and `coplot`.

### Examples

```
class(fo <- y ~ x1*x2) # "formula"
fo
typeof(fo) # R internal : "language"
terms(fo)

environment(fo)
environment(as.formula("y ~ x"))
environment(as.formula("y ~ x", env = new.env()))

Create a formula for a model with a large number of variables:
xnam <- paste0("x", 1:25)
fmla <- as.formula(paste("y ~ ", paste(xnam, collapse= "+")))
```

---

formula.nls

*Extract Model Formula from nls Object*

---

### Description

Returns the model used to fit object.

### Usage

```
S3 method for class nls
formula(x, ...)
```

**Arguments**

- x an object inheriting from class "nls", representing a nonlinear least squares fit.
- ... further arguments passed to or from other methods.

**Value**

a formula representing the model used to obtain object.

**friedman.test**

*Friedman Rank Sum Test*

**Description**

Performs a Friedman rank sum test with unreplicated blocked data.

**Usage**

```
friedman.test(y, ...)
Default S3 method:
friedman.test(y, groups, blocks, ...)
S3 method for class formula
friedman.test(formula, data, subset, na.action, ...)
```

**Arguments**

- y either a numeric vector of data values, or a data matrix.
- groups a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
- blocks a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
- formula a formula of the form a ~ b | c, where a, b and c give the data values and corresponding groups and blocks, respectively.
- data an optional matrix or data frame (or similar: see [model.frame](#)) containing the variables in the formula formula. By default the variables are taken from [environment\(formula\)](#).

|           |                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------|
| subset    | an optional vector specifying a subset of observations to be used.                                                         |
| na.action | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> . |
| ...       | further arguments to be passed to or from methods.                                                                         |

## Details

`friedman.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of `groups` and `blocks`) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of `blocks`, the location parameter of `y` is the same in each of the groups.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. NA's are not allowed in `groups` or `blocks`; if `y` contains NA's, corresponding blocks are removed.

## Value

A list with class "htest" containing the following components:

|           |                                                                                           |
|-----------|-------------------------------------------------------------------------------------------|
| statistic | the value of Friedman's chi-squared statistic.                                            |
| parameter | the degrees of freedom of the approximate chi-squared distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                  |
| method    | the character string "Friedman rank sum test".                                            |
| data.name | a character string giving the names of the data.                                          |

| <code>x, ...</code>   | <code>R</code> objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, or a contingency table object of class “table” or “ftable”. |
| <code>exclude</code>  | values to use in the <code>exclude</code> argument of <code>factor</code> when interpreting non-factor objects.                                                                                                         |
| <code>row.vars</code> | a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the rows of the flat contingency table.                                                |

|          |                                                                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col.vars | a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the columns of the flat contingency table. |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Details

`ftable` creates ‘flat’ contingency tables. Similar to the usual contingency tables, these contain the counts of each combination of the levels of the variables (factors) involved. This information is then re-arranged as a matrix whose rows and columns correspond to unique combinations of the levels of the row and column variables (as specified by `row.vars` and `col.vars`, respectively). The combinations are created by looping over the variables in reverse order (so that the levels of the left-most variable vary the slowest). Displaying a contingency table in this flat matrix form (via `print.ftable`, the print method for objects of class “`ftable`”) is often preferable to showing it as a higher-dimensional array.

`ftable` is a generic function. Its default method, `ftable.default`, first creates a contingency table in array form from all arguments except `row.vars` and `col.vars`. If the first argument is of class “`table`”, it represents a contingency table and is used as is; if it is a flat table of class “`ftable`”, the information it contains is converted to the usual array representation using `as.ftable`. Otherwise, the arguments should be R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, which are cross-tabulated using `table`. Then, the arguments `row.vars` and `col.vars` are used to collapse the contingency table into flat form. If neither of these two is given, the last variable is used for the columns. If both are given and their union is a proper subset of all variables involved, the other variables are summed out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed to `table` to control how the variable names are displayed; see the last example below.

Function `ftable.formula` provides a formula method for creating flat contingency tables.

There are methods for `as.table` and `as.data.frame`.

## Value

`ftable` returns an object of class “`ftable`”, which is a matrix with counts of each combination of the levels of variables with information on the names and levels of the (row and columns) variables stored as attributes “`row.vars`” and “`col.vars`”.

## See Also

`ftable.formula` for the formula interface (which allows a `data = .` argument); `read.ftable` for information on reading, writing and coercing flat contingency tables; `table` for ordinary cross-tabulation; `xtabs` for formula-based cross-tabulation.

## Examples

```
Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

Start with a data frame.
x <- ftable(mtcars[c("cyl", "vs", "am", "gear")])
x
ftable(x, row.vars = c(2, 4))
```

---

```
Start with expressions, use table()s "dnn" to change labels
ftable(mtcars$cyl, mtcars$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
 dnn = c("Cylinders", "V/S", "Transmission", "Gears"))
```

---

**ftable.formula***Formula Notation for Flat Contingency Tables***Description**

Produce or manipulate a flat contingency table using formula notation.

**Usage**

```
S3 method for class formula
ftable(formula, data = NULL, subset, na.action, ...)
```

**Arguments**

|                  |                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>formula</b>   | a formula object with both left and right hand sides specifying the column and row variables of the flat table.                                                      |
| <b>data</b>      | a data frame, list or environment (or similar: see <a href="#">model.frame</a> ) containing the variables to be cross-tabulated, or a contingency table (see below). |
| <b>subset</b>    | an optional vector specifying a subset of observations to be used. Ignored if data is a contingency table.                                                           |
| <b>na.action</b> | a function which indicates what should happen when the data contain NAs. Ignored if data is a contingency table.                                                     |
| <b>...</b>       | further arguments to the default ftable method may also be passed as arguments, see <a href="#">ftable.default</a> .                                                 |

**Details**

This is a method of the generic function [ftable](#).

The left and right hand side of formula specify the column and row variables, respectively, of the flat contingency table to be created. Only the + operator is allowed for combining the variables. A . may be used once in the formula to indicate inclusion of all the remaining variables.

If data is an object of class "table" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat contingency table (i.e., an object of class "ftable"), it should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, na.action is applied to the data to handle missing values, and, after possibly selecting a subset of the data as specified by the subset argument, a contingency table is computed from the variables.

The contingency table is then collapsed to a flat table, according to the row and column variables specified by formula.

**Value**

A flat contingency table which contains the counts of each combination of the levels of the variables, collapsed into a matrix for suitably displaying the counts.

**See Also**

[ftable](#), [ftable.default](#); [table](#).

**Examples**

```
Titanic
x <- ftable(Survived ~ ., data = Titanic)
x
ftable(Sex ~ Class + Age, data = x)
```

**Description**

Density, distribution function, quantile function and random generation for the Gamma distribution with parameters `shape` and `scale`.

**Usage**

```
dgamma(x, shape, rate = 1, scale = 1/rate, log = FALSE)
pgamma(q, shape, rate = 1, scale = 1/rate, lower.tail = TRUE,
 log.p = FALSE)
qgamma(p, shape, rate = 1, scale = 1/rate, lower.tail = TRUE,
 log.p = FALSE)
rgamma(n, shape, rate = 1, scale = 1/rate)
```

**Arguments**

|                           |                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>         | vector of quantiles.                                                                                      |
| <code>p</code>            | vector of probabilities.                                                                                  |
| <code>n</code>            | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>rate</code>         | an alternative way to specify the scale.                                                                  |
| <code>shape, scale</code> | shape and scale parameters. Must be positive, <code>scale</code> strictly.                                |
| <code>log, log.p</code>   | logical; if <code>TRUE</code> , probabilities/densities $p$ are returned as $\log(p)$ .                   |
| <code>lower.tail</code>   | logical; if <code>TRUE</code> (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .        |

**Details**

If `scale` is omitted, it assumes the default value of 1.

The Gamma distribution with parameters `shape =  $\alpha$`  and `scale =  $\sigma$`  has density

$$f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\sigma}$$

for  $x \geq 0$ ,  $\alpha > 0$  and  $\sigma > 0$ . (Here  $\Gamma(\alpha)$  is the function implemented by R's [gamma](#)() and defined in its help. Note that  $a = 0$  corresponds to the trivial distribution with all mass at point 0.)

The mean and variance are  $E(X) = \alpha\sigma$  and  $Var(X) = \alpha\sigma^2$ .

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is

```
-pgamma(t, ..., lower = FALSE, log = TRUE)
```

Note that for smallish values of shape (and moderate scale) a large parts of the mass of the Gamma distribution is on values of  $x$  so near zero that they will be represented as zero in computer arithmetic. So rgamma may well return values which will be represented as zero. (This will also happen for very large values of scale since the actual generation is done for scale = 1.)

### Value

dgamma gives the density, pgamma gives the distribution function, qgamma gives the quantile function, and rgamma generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rgamma, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

### Note

The S (Becker *et al* (1988) parametrization was via shape and rate: S had no scale parameter. In R 2.x.y scale took precedence over rate, but now it is an error to supply both.

pgamma is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1 (and by ‘Numerical Recipes’) this is

$$P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

$P(a, x)$  is pgamma(x, a). Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function  $\gamma(a, x)$  as  $\gamma(a, x) = \int_0^x t^{a-1} e^{-t} dt$ , i.e., pgamma(x, a) \* gamma(a). Yet others use the ‘upper’ incomplete gamma function,

$$\Gamma(a, x) = \int_x^\infty t^{a-1} e^{-t} dt,$$

which can be computed by pgamma(x, a, lower = FALSE) \* gamma(a).

Note however that pgamma(x, a, ...) currently requires  $a > 0$ , whereas the incomplete gamma function is also defined for negative  $a$ . In that case, you can use gamma\_inc(a, x) (for  $\Gamma(a, x)$ ) from package **gsl**.

that cannot be represented accurately (and most of those as zero)
pgamma(.Machine$double.xmin, 0.001)
pgamma(5e-324, 0.001) # on most machines 5e-324 is the smallest
representable non-zero number
table(rgamma(1e4, 0.001) == 0)/1e4
```

## Description

Density, distribution function, quantile function and random generation for the geometric distribution with parameter `prob`.

## Usage

```
dgeom(x, prob, log = FALSE)
pgeom(q, prob, lower.tail = TRUE, log.p = FALSE)
qgeom(p, prob, lower.tail = TRUE, log.p = FALSE)
rgeom(n, prob)
```

## Arguments

|                         |                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs. |
| <code>p</code>          | vector of probabilities.                                                                                         |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required.        |
| <code>prob</code>       | probability of success in each trial. $0 < \text{prob} \leq 1$ .                                                 |
| <code>log, log.p</code> | logical; if TRUE, probabilities p are given as log(p).                                                           |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                            |

## Details

The geometric distribution with `prob = p` has density

$$p(x) = p(1 - p)^x$$

for  $x = 0, 1, 2, \dots, 0 < p \leq 1$ .

If an element of `x` is not integer, the result of `dgeom` is zero, with a warning.

The quantile is defined as the smallest value  $x$  such that  $F(x) \geq p$ , where  $F$  is the distribution function.

## Value

`dgeom` gives the density, `pgeom` gives the distribution function, `qgeom` gives the quantile function, and `rgeom` generates random deviates.

Invalid `prob` will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rgeom`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

## Source

`dgeom` computes via `dbinom`, using code contributed by Catherine Loader (see [dbinom](#)).

`pgeom` and `qgeom` are based on the closed-form formulae.

`rgeom` uses the derivation as an exponential mixture of Poissons, see

Devroye, L. (1986) *Non-Uniform Random Variate Generation*. Springer-Verlag, New York. Page 480.

## See Also

[Distributions](#) for other standard distributions, including [dnbinom](#) for the negative binomial which generalizes the geometric distribution.

## Examples

```
qgeom((1:9)/10, prob = .2)
Ni <- rgeom(20, prob = 1/4); table(factor(Ni, 0:max(Ni)))
```

---

**getInitial***Get Initial Parameter Estimates*

---

**Description**

This function evaluates initial parameter estimates for a nonlinear regression model. If `data` is a parameterized data frame or `pframe` object, its `parameters` attribute is returned. Otherwise the object is examined to see if it contains a call to a `selfStart` object whose `initial` attribute can be evaluated.

**Usage**

```
getInitial(object, data, ...)
```

**Arguments**

- |                     |                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a formula or a <code>selfStart</code> model that defines a nonlinear regression model                                  |
| <code>data</code>   | a data frame in which the expressions in the formula or arguments to the <code>selfStart</code> model can be evaluated |
| <code>...</code>    | optional additional arguments                                                                                          |

**Value**

A named numeric vector or list of starting estimates for the parameters. The construction of many `selfStart` models is such that these "starting" estimates are, in fact, the converged parameter estimates.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

**Examples**

```
PurTrt <- Puromycin[Puromycin$state == "treated",]
print(getInitial(rate ~ SSmicmen(conc, Vm, K), PurTrt), digits = 3)
```

---

glm*Fitting Generalized Linear Models*

---

**Description**

`glm` is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

**Usage**

```
glm(formula, family = gaussian, data, weights, subset,
 na.action, start = NULL, etastart, mustart, offset,
 control = list(...), model = TRUE, method = "glm.fit",
 x = FALSE, y = TRUE, contrasts = NULL, ...)

glm.fit(x, y, weights = rep(1, nobs),
 start = NULL, etastart = NULL, mustart = NULL,
 offset = rep(0, nobs), family = gaussian(),
 control = list(), intercept = TRUE)

S3 method for class glm
weights(object, type = c("prior", "working"), ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | an object of class “ <a href="#">formula</a> ” (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under ‘Details’.                                                                                                                                                               |
| <code>family</code>    | a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See <a href="#">family</a> for details of family functions.)                                                                                                |
| <code>data</code>      | an optional data frame, list or environment (or object coercible by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>glm</code> is called.                                                         |
| <code>weights</code>   | an optional vector of ‘prior weights’ to be used in the fitting process. Should be <code>NULL</code> or a numeric vector.                                                                                                                                                                                                                                                |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <a href="#">options</a> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . Another possible value is <code>NULL</code> , no action. Value <code>na.exclude</code> can be useful. |
| <code>start</code>     | starting values for the parameters in the linear predictor.                                                                                                                                                                                                                                                                                                              |
| <code>etastart</code>  | starting values for the linear predictor.                                                                                                                                                                                                                                                                                                                                |
| <code>mustart</code>   | starting values for the vector of means.                                                                                                                                                                                                                                                                                                                                 |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| offset    | this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more <code>offset</code> terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See <code>model.offset</code> .                                                                                                                                                |
| control   | a list of parameters for controlling the fitting process. For <code>glm.fit</code> this is passed to <code>glm.control</code> .                                                                                                                                                                                                                                                                                                                                                                                                    |
| model     | a logical value indicating whether <i>model frame</i> should be included as a component of the returned value.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| method    | the method to be used in fitting the model. The default method " <code>glm.fit</code> " uses iteratively reweighted least squares (IWLS); the alternative " <code>model.frame</code> " returns the model frame and does no fitting.<br><br>User-supplied fitting functions can be supplied either as a function or a character string naming a function, with a function which takes the same arguments as <code>glm.fit</code> . If specified as a character string it is looked up from within the <code>stats</code> namespace. |
| x, y      | For <code>glm</code> : logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value.<br><br>For <code>glm.fit</code> : x is a design matrix of dimension n * p, and y is a vector of observations of length n.                                                                                                                                                                                                                        |
| contrasts | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| intercept | logical. Should an intercept be included in the <i>null</i> model?                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| object    | an object inheriting from class "glm".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| type      | character, partial matching allowed. Type of weights to extract from the fitted model object.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ...       | For <code>glm</code> : arguments to be used to form the default <code>control</code> argument if it is not supplied directly.<br><br>For <code>weights</code> : further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                 |

## Details

A typical predictor has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for `response`. For binomial and quasibinomial families the `response` can also be specified as a `factor` (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A `terms` specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with any duplicates removed.

A specification of the form `first:second` indicates the the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the *cross* of `first` and `second`. This is the same as `first + second + first:second`.

The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a `terms` object as the formula.

Non-NULL weights can be used to indicate that different observations have different dispersions (with the values in `weights` being inversely proportional to the dispersions); or equivalently, when the elements of `weights` are positive integers  $w_i$ , that each response  $y_i$  is the mean of  $w_i$  unit-weight observations. For a binomial GLM prior weights are used to give the number of trials when the response is the proportion of successes: they would rarely be used for a Poisson GLM.

`glm.fit` is the workhorse function: it is not normally called directly but can be more efficient where the response vector and design matrix have already been calculated.

If more than one of `etastart`, `start` and `mustart` is specified, the first in the list will be used. It is often advisable to supply starting values for a `quasi` family, and also for families with unusual links such as `gaussian("log")`.

All of `weights`, `subset`, `offset`, `etastart` and `mustart` are evaluated in the same way as variables in `formula`, that is first in `data` and then in the environment of `formula`.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables & Ripley (2002, pp. 197–8).

## Value

`glm` returns an object of class inheriting from “`glm`” which inherits from the class “`lm`”. See later in this section. If a non-standard method is used, the object will also inherit from the class (if any) returned by that function.

The function `summary` (i.e., `summary.glm`) can be used to obtain or print a summary of the results and the function `anova` (i.e., `anova.glm`) to produce an analysis of variance table.

The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` can be used to extract various useful features of the value returned by `glm`.

`weights` extracts a vector of weights, one for each case in the fit (after subsetting and `na.action`).

An object of class “`glm`” is a list containing at least the following components:

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>coefficients</code>      | a named vector of coefficients                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>residuals</code>         | the <i>working</i> residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their working residuals are NA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>fitted.values</code>     | the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>rank</code>              | the numeric rank of the fitted linear model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>family</code>            | the <code>family</code> object used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>linear.predictors</code> | the linear fit on link scale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>deviance</code>          | up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>aic</code>               | A version of Akaike’s <i>An Information Criterion</i> , minus twice the maximized log-likelihood plus twice the number of parameters, computed by the <code>aic</code> component of the family. For binomial and Poisson families the dispersion is fixed at one and the number of parameters is the number of coefficients. For gaussian, Gamma and inverse gaussian families the dispersion is estimated from the residual deviance, and the number of parameters is the number of coefficients plus one. For a gaussian family the MLE of the dispersion is used so this is a valid value of AIC, but for Gamma and inverse gaussian families it is not. For families fitted by quasi-likelihood the value is NA. |
| <code>null.deviance</code>     | The deviance for the null model, comparable with <code>deviance</code> . The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>iter</code>              | the number of iterations of IWLS used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>weights</code>           | the <i>working</i> weights, that is the weights in the final iteration of the IWLS fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|               |                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------|
| prior.weights | the weights initially supplied, a vector of 1s if none were.                                      |
| df.residual   | the residual degrees of freedom.                                                                  |
| df.null       | the residual degrees of freedom for the null model.                                               |
| y             | if requested (the default) the y vector used. (It is a vector even for a binomial model.)         |
| x             | if requested, the model matrix.                                                                   |
| model         | if requested (the default), the model frame.                                                      |
| converged     | logical. Was the IWLS algorithm judged to have converged?                                         |
| boundary      | logical. Is the fitted value on the boundary of the attainable values?                            |
| call          | the matched call.                                                                                 |
| formula       | the formula supplied.                                                                             |
| terms         | the <code>terms</code> object used.                                                               |
| data          | the <code>data</code> argument.                                                                   |
| offset        | the offset vector used.                                                                           |
| control       | the value of the <code>control</code> argument used.                                              |
| method        | the name of the fitter function used, currently always " <code>glm.fit</code> ".                  |
| contrasts     | (where relevant) the contrasts used.                                                              |
| xlevels       | (where relevant) a record of the levels of the factors used in fitting.                           |
| na.action     | (where relevant) information returned by <code>model.frame</code> on the special handling of NAs. |

In addition, non-empty fits will have components `qr`, `R` and `effects` relating to the final weighted linear fit.

Objects of class "glm" are normally of class `c("glm", "lm")`, that is inherit from class "lm", and well-designed methods for class "lm" will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class "glm" such as `residuals` and `weights` do **not** just pick out the component of the fit with the same name.

If a `binomial` `glm` model was specified by giving a two-column response, the weights returned by `prior.weights` are the total numbers of cases (factored by the supplied case weights) and the component `y` of the result is the proportion of successes.

## Fitting functions

The argument `method` serves two purposes. One is to allow the model frame to be recreated with no fitting. The other is to allow the default fitting function `glm.fit` to be replaced by a function which takes the same arguments and uses a different fitting algorithm. If `glm.fit` is supplied as a character string it is used to search for a function of that name, starting in the `stats` namespace.

The class of the object return by the fitter (if any) will be prepended to the class returned by `glm`.

## Author(s)

The original R implementation of `glm` was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team. The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

---

glm.controlAuxiliary for Controlling GLM Fitting

---

**Description**

Auxiliary function for `glm` fitting. Typically only used internally by `glm.fit`, but may be used to construct a control argument to either function.

**Usage**

```
glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)
```

**Arguments**

|                      |                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>epsilon</code> | positive convergence tolerance $\epsilon$ ; the iterations converge when $ dev - dev_{old} /( dev  + 0.1) < \epsilon$ . |
| <code>maxit</code>   | integer giving the maximal number of IWLS iterations.                                                                   |
| <code>trace</code>   | logical indicating if output should be produced for each iteration.                                                     |

**Details**

The control argument of `glm` is by default passed to the control argument of `glm.fit`, which uses its elements as arguments to `glm.control`: the latter provides defaults and sanity checking.

If `epsilon` is small (less than  $10^{-10}$ ) it is also used as the tolerance for the detection of collinearity in the least squares solution.

When `trace` is true, calls to `cat` produce the output for each IWLS iteration. Hence, `options(digits = *)` can be used to increase the precision, see the example.

**Value**

A list with components named as the arguments.

**See Also**

`glm.fit`, the fitting procedure used by `glm`.

**Examples**

```
A variation on example(glm) :

Annette Dobsons example ...
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
oo <- options(digits = 12) # to see more when tracing :
glm.D93X <- glm(counts ~ outcome + treatment, family = poisson(),
```

```
trace = TRUE, epsilon = 1e-14)
options(oo)
coef(glm.D93X) # the last two are closer to 0 than in ?glms glm.D93
```

## Description

These functions are all [methods](#) for class `glm` or `summary.glm` objects.

## Usage

```
S3 method for class glm
family(object, ...)

S3 method for class glm
residuals(object, type = c("deviance", "pearson", "working",
 "response", "partial"), ...)
```

## Arguments

|                     |                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object of class <code>glm</code> , typically the result of a call to <a href="#">glm</a> .                                                |
| <code>type</code>   | the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial". |
| <code>...</code>    | further arguments passed to or from other methods.                                                                                           |

## Details

The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How `residuals` treats cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear, with residual value NA. See also [naresid](#).

For fits done with `y = FALSE` the response values are computed from other components.

hclust

*Hierarchical Clustering***Description**

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

**Usage**

```
hclust(d, method = "complete", members = NULL)

S3 method for class hclust
plot(x, labels = NULL, hang = 0.1,
 axes = TRUE, frame.plot = FALSE, ann = TRUE,
 main = "Cluster Dendrogram",
 sub = NULL, xlab = NULL, ylab = "Height", ...)
```

**Arguments**

|                                                                              |                                                                                                                                                                                              |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>d</code>                                                               | a dissimilarity structure as produced by <code>dist</code> .                                                                                                                                 |
| <code>method</code>                                                          | the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward", "single", "complete", "average", "mcquitty", "median" or "centroid".                     |
| <code>members</code>                                                         | NULL or a vector with length size of <code>d</code> . See the 'Details' section.                                                                                                             |
| <code>x</code>                                                               | an object of the type produced by <code>hclust</code> .                                                                                                                                      |
| <code>hang</code>                                                            | The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.                                          |
| <code>labels</code>                                                          | A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If <code>labels = FALSE</code> no labels at all are plotted. |
| <code>axes</code> , <code>frame.plot</code> , <code>ann</code>               | logical flags as in <a href="#">plot.default</a> .                                                                                                                                           |
| <code>main</code> , <code>sub</code> , <code>xlab</code> , <code>ylab</code> | character strings for <code>title</code> . <code>sub</code> and <code>xlab</code> have a non-NULL default when there's a <code>tree\$call</code> .                                           |
| <code>...</code>                                                             | Further graphical arguments. E.g. <code>cex</code> controls the size of the labels (if plotted) in the same way as <a href="#">text</a> .                                                    |

## Details

This function performs a hierarchical cluster analysis using a set of dissimilarities for the  $n$  objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. *Ward's* minimum variance method aims at finding compact, spherical clusters. The *complete linkage* method finds similar clusters. The *single linkage* method (which is closely related to the minimal spanning tree) adopts a ‘friends of friends’ clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods “median” and “centroid” are *not* leading to a *monotone distance* measure, or equivalently the resulting dendrograms can have so called *inversions* (which are hard to interpret).

If `members` != `NULL`, then `d` is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and `members` gives the number of observations per cluster. This way the hierarchical cluster algorithm can be ‘started in the middle of the dendrogram’, e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without `hclust` itself) only for a limited number of distance/linkage combinations, the simplest one being squared Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for  $n$  observations there are  $n - 1$  merges, there are  $2^{(n-1)}$  possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in `hclust` is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

## Value

An object of class **`hclust`** which describes the tree produced by the clustering process. The object is a list with components:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>merge</code>       | an $n - 1$ by 2 matrix. Row $i$ of <code>merge</code> describes the merging of clusters at step $i$ of the clustering. If an element $j$ in the row is negative, then observation $-j$ was merged at this stage. If $j$ is positive then the merge was with the cluster formed at the (earlier) stage $j$ of the algorithm. Thus negative entries in <code>merge</code> indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons. |
| <code>height</code>      | a set of $n - 1$ real values (non-decreasing for ultrametric trees). The clustering <code>height</code> : that is, the value of the criterion associated with the clustering method for the particular agglomeration.                                                                                                                                                                                                                                                          |
| <code>order</code>       | a vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix <code>merge</code> will not have crossings of the branches.                                                                                                                                                                                                                                                                |
| <code>labels</code>      | labels for each of the objects being clustered.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>call</code>        | the call which produced the result.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>method</code>      | the cluster method that has been used.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>dist.method</code> | the distance that has been used to create <code>d</code> (only returned if the distance object has a “ <code>method</code> ” attribute).                                                                                                                                                                                                                                                                                                                                       |

There are `print`, `plot` and `identify` (see `identify.hclust`) methods and the `rect.hclust()` function for `hclust` objects.

### Author(s)

The `hclust` function is based on Fortran code contributed to STATLIB by F. Murtagh.

For the Lance–Williams formula and methods that apply it generally, see `agnes` from package **cluster**.

### Examples

```
require(graphics)

hc <- hclust(dist(USArrests), "ave")
plot(hc)
plot(hc, hang = -1)

Do the same with centroid clustering and squared Euclidean distance,
cut the tree into ten clusters and reconstruct the upper part of the
tree from the cluster centers.
hc <- hclust(dist(USArrests)^2, "cen")
memb <- cutree(hc, k = 10)
cent <- NULL
for(k in 1:10){
 cent <- rbind(cent, colMeans(USArrests[memb == k, , drop = FALSE]))
}
hc1 <- hclust(dist(cent)^2, method = "cen", members = table(memb))
opar <- par(mfrow = c(1, 2))
plot(hc, labels = FALSE, hang = -1, main = "Original Tree")
plot(hc1, labels = FALSE, hang = -1, main = "Re-start from 10 clusters")
par(opar)
```

---

heatmap*Draw a Heat Map*

---

**Description**

A heat map is a false color image (basically `image(t(x))`) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.

**Usage**

```
heatmap(x, Rowv = NULL, Colv = if(symm)"Rowv" else NULL,
 distfun = dist, hclustfun = hclust,
 reorderfun = function(d, w) reorder(d, w),
 add.expr, symm = FALSE, revC = identical(Colv, "Rowv"),
 scale = c("row", "column", "none"), na.rm = TRUE,
 margins = c(5, 5), ColSideColors, RowSideColors,
 cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc),
 labRow = NULL, labCol = NULL, main = NULL,
 xlab = NULL, ylab = NULL,
 keep.dendro = FALSE, verbose = getOption("verbose"), ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | numeric matrix of the values to be plotted.                                                                                                                                                                                                                                                                                                                                      |
| <code>Rowv</code>       | determines if and how the <i>row</i> dendrogram should be computed and reordered. Either a <code>dendrogram</code> or a vector of values used to reorder the row dendrogram or <code>NA</code> to suppress any row dendrogram (and reordering) or by default, <code>NULL</code> , see ‘Details’ below.                                                                           |
| <code>Colv</code>       | determines if and how the <i>column</i> dendrogram should be reordered. Has the same options as the <code>Rowv</code> argument above and <i>additionally</i> when <code>x</code> is a square matrix, <code>Colv = "Rowv"</code> means that columns should be treated identically to the rows (and so if there is to be no row dendrogram there will not be a column one either). |
| <code>distfun</code>    | function used to compute the distance (dissimilarity) between both rows and columns. Defaults to <code>dist</code> .                                                                                                                                                                                                                                                             |
| <code>hclustfun</code>  | function used to compute the hierarchical clustering when <code>Rowv</code> or <code>Colv</code> are not dendrograms. Defaults to <code>hclust</code> . Should take as argument a result of <code>distfun</code> and return an object to which <code>as.dendrogram</code> can be applied.                                                                                        |
| <code>reorderfun</code> | <code>function(d, w)</code> of dendrogram and weights for reordering the row and column dendograms. The default uses <code>reorder.dendrogram</code> .                                                                                                                                                                                                                           |
| <code>add.expr</code>   | expression that will be evaluated after the call to <code>image</code> . Can be used to add components to the plot.                                                                                                                                                                                                                                                              |
| <code>symm</code>       | logical indicating if <code>x</code> should be treated <b>symmetrically</b> ; can only be true when <code>x</code> is a square matrix.                                                                                                                                                                                                                                           |
| <code>revC</code>       | logical indicating if the column order should be <b>reversed</b> for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.                                                                                                                                                                                                                            |

|                  |                                                                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scale            | character indicating if the values should be centered and scaled in either the row direction or the column direction, or none. The default is "row" if <code>symm</code> false, and "none" otherwise. |
| na.rm            | logical indicating whether NA's should be removed.                                                                                                                                                    |
| margins          | numeric vector of length 2 containing the margins (see <code>par</code> ( <code>mar = *</code> )) for column and row names, respectively.                                                             |
| ColSideColors    | (optional) character vector of length <code>ncol(x)</code> containing the color names for a horizontal side bar that may be used to annotate the columns of <code>x</code> .                          |
| RowSideColors    | (optional) character vector of length <code>nrow(x)</code> containing the color names for a vertical side bar that may be used to annotate the rows of <code>x</code> .                               |
| cexRow, cexCol   | positive numbers, used as <code>cex.axis</code> in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.                                      |
| labRow, labCol   | character vectors with row and column labels to use; these default to <code>rownames(x)</code> or <code>colnames(x)</code> , respectively.                                                            |
| main, xlab, ylab | main, x- and y-axis titles; defaults to none.                                                                                                                                                         |
| keep.dendro      | logical indicating if the dendrogram(s) should be kept as part of the result (when <code>Rowv</code> and/or <code>Colv</code> are not NA).                                                            |
| verbose          | logical indicating if information should be printed.                                                                                                                                                  |
| ...              | additional arguments passed on to <code>image</code> , e.g., <code>col</code> specifying the colors.                                                                                                  |

## Details

If either `Rowv` or `Colv` are dendrograms they are honored (and not reordered). Otherwise, dendrograms are computed as `dd <- as.dendrogram(hclustfun(distfun(X)))` where `X` is either `x` or `t(x)`.

If either is a vector (of 'weights') then the appropriate dendrogram is reordered according to the supplied values subject to the constraints imposed by the dendrogram, by `reorder(dd, Rowv)`, in the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram is by the mean value of the rows/columns, i.e., in the case of rows, `Rowv <- rowMeans(x, na.rm = na.rm)`. If either is NA, no reordering will be done for the corresponding side.

By default (`scale = "row"`) the rows are scaled to have mean zero and standard deviation one. There is some empirical evidence from genomic plotting that this is useful.

The default colors are not pretty. Consider using enhancements such as the **RColorBrewer** package.

## Value

Invisibly, a list with components

|        |                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------|
| rowInd | row index permutation vector as returned by <code>order.dendrogram</code> .                             |
| colInd | column index permutation vector.                                                                        |
| Rowv   | the row dendrogram; only if input <code>Rowv</code> was not NA and <code>keep.dendro</code> is true.    |
| Colv   | the column dendrogram; only if input <code>Colv</code> was not NA and <code>keep.dendro</code> is true. |

**Note**

Unless `Rowv = NA` (or `Colv = NA`), the original rows and columns are reordered *in any case* to match the dendrogram, e.g., the rows by `order.dendrogram(Rowv)` where `Rowv` is the (possibly `reorder()`ed) row dendrogram.

`heatmap()` uses `layout` and draws the `image` in the lower right corner of a 2x2 layout. Consequently, it can **not** be used in a multi column/row layout, i.e., when `par(mfrow = *)` or `(mfcol = *)` has been called.

**Examples**

```
require(graphics); require(grDevices)
x <- as.matrix(mtcars)
rc <- rainbow(nrow(x), start = 0, end = .3)
cc <- rainbow(ncol(x), start = 0, end = .3)
hv <- heatmap(x, col = cm.colors(256), scale = "column",
 RowSideColors = rc, ColSideColors = cc, margins = c(5,10),
 xlab = "specification variables", ylab = "Car Models",
 main = "heatmap(<Mtcars data>, ..., scale = \"column\")")
utils::str(hv) # the two re-ordering index vectors

no column dendrogram (nor reordering) at all:
heatmap(x, Colv = NA, col = cm.colors(256), scale = "column",
 RowSideColors = rc, margins = c(5,10),
 xlab = "specification variables", ylab = "Car Models",
 main = "heatmap(<Mtcars data>, ..., scale = \"column\")")

"no nothing"
heatmap(x, Rowv = NA, Colv = NA, scale = "column",
 main = "heatmap(*, NA, NA) ~ image(t(x))")

round(Ca <- cor(attitude), 2)
symnum(Ca) # simple graphic
heatmap(Ca, symm = TRUE, margins = c(6,6)) # with reorder()
heatmap(Ca, Rowv = FALSE, symm = TRUE, margins = c(6,6)) # _NO_ reorder()
slightly artificial with color bar, without and with ordering:
cc <- rainbow(nrow(Ca))
heatmap(Ca, Rowv = FALSE, symm = TRUE, RowSideColors = cc, ColSideColors = cc,
 margins = c(6,6))
heatmap(Ca,symm = TRUE, RowSideColors = cc, ColSideColors = cc,
 margins = c(6,6))

For variable clustering, rather use distance based on cor():
symnum(cU <- cor(USJudgeRatings))

hU <- heatmap(cU, Rowv = FALSE, symm = TRUE, col = topo.colors(16),
 distfun = function(c) as.dist(1 - c), keep.dendro = TRUE)
```

```
The Correlation matrix with same reordering:
round(100 * cU[hU[[1]], hU[[2]]])
The column dendrogram:
utils::str(hU$Colv)
```

**HoltWinters***Holt-Winters Filtering***Description**

Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

**Usage**

```
HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL,
 seasonal = c("additive", "multiplicative"),
 start.periods = 2, l.start = NULL, b.start = NULL,
 s.start = NULL,
 optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1),
 optim.control = list())
```

**Arguments**

|                      |                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>             | An object of class <code>ts</code>                                                                                                                                                                        |
| <b>alpha</b>         | <i>alpha</i> parameter of Holt-Winters Filter.                                                                                                                                                            |
| <b>beta</b>          | <i>beta</i> parameter of Holt-Winters Filter. If set to FALSE, the function will do exponential smoothing.                                                                                                |
| <b>gamma</b>         | <i>gamma</i> parameter used for the seasonal component. If set to FALSE, an non-seasonal model is fitted.                                                                                                 |
| <b>seasonal</b>      | Character string to select an "additive" (the default) or "multiplicative" seasonal model. The first few characters are sufficient. (Only takes effect if <i>gamma</i> is non-zero).                      |
| <b>start.periods</b> | Start periods used in the autodetection of start values. Must be at least 2.                                                                                                                              |
| <b>l.start</b>       | Start value for level ( $a[0]$ ).                                                                                                                                                                         |
| <b>b.start</b>       | Start value for trend ( $b[0]$ ).                                                                                                                                                                         |
| <b>s.start</b>       | Vector of start values for the seasonal component ( $s_1[0] \dots s_p[0]$ )                                                                                                                               |
| <b>optim.start</b>   | Vector with named components <i>alpha</i> , <i>beta</i> , and <i>gamma</i> containing the starting values for the optimizer. Only the values needed must be specified. Ignored in the one-parameter case. |
| <b>optim.control</b> | Optional list with additional control parameters passed to <code>optim</code> if this is used. Ignored in the one-parameter case.                                                                         |

## Details

The additive Holt-Winters prediction function (for time series with period length p) is

$$\hat{Y}[t+h] = a[t] + hb[t] + s[t-p+1+(h-1) \bmod p],$$

where  $a[t]$ ,  $b[t]$  and  $s[t]$  are given by

$$a[t] = \alpha(Y[t] - s[t-p]) + (1-\alpha)(a[t-1] + b[t-1])$$

$$b[t] = \beta(a[t] - a[t-1]) + (1-\beta)b[t-1]$$

$$s[t] = \gamma(Y[t] - a[t]) + (1-\gamma)s[t-p]$$

The multiplicative Holt-Winters prediction function (for time series with period length p) is

$$\hat{Y}[t+h] = (a[t] + hb[t]) \times s[t-p+1+(h-1) \bmod p].$$

where  $a[t]$ ,  $b[t]$  and  $s[t]$  are given by

$$a[t] = \alpha(Y[t]/s[t-p]) + (1-\alpha)(a[t-1] + b[t-1])$$

$$b[t] = \beta(a[t] - a[t-1]) + (1-\beta)b[t-1]$$

$$s[t] = \gamma(Y[t]/a[t]) + (1-\gamma)s[t-p]$$

The data in  $x$  are required to be non-zero for a multiplicative model, but it makes most sense if they are all positive.

The function tries to find the optimal values of  $\alpha$  and/or  $\beta$  and/or  $\gamma$  by minimizing the squared one-step prediction error if they are NULL (the default). `optimize` will be used for the single-parameter case, and `optim` otherwise.

For seasonal models, start values for  $a$ ,  $b$  and  $s$  are inferred by performing a simple decomposition in trend and seasonal component using moving averages (see function `decompose`) on the `start.periods` first periods (a simple linear regression on the trend component is used for starting level and trend). For level/trend-models (no seasonal component), start values for  $a$  and  $b$  are  $x[2]$  and  $x[2] - x[1]$ , respectively. For level-only models (ordinary exponential smoothing), the start value for  $a$  is  $x[1]$ .

## Value

An object of class "HoltWinters", a list with components:

|                           |                                                                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fitted</code>       | A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time t and not at the end of the series). |
| <code>x</code>            | The original series                                                                                                                                                                                       |
| <code>alpha</code>        | alpha used for filtering                                                                                                                                                                                  |
| <code>beta</code>         | beta used for filtering                                                                                                                                                                                   |
| <code>gamma</code>        | gamma used for filtering                                                                                                                                                                                  |
| <code>coefficients</code> | A vector with named components <code>a</code> , <code>b</code> , <code>s1</code> , ..., <code>sp</code> containing the estimated values for the level, trend and seasonal components                      |
| <code>seasonal</code>     | The specified seasonal parameter                                                                                                                                                                          |
| <code>SSE</code>          | The final sum of squared errors achieved in optimizing                                                                                                                                                    |
| <code>call</code>         | The call used                                                                                                                                                                                             |

**Examples**

```
require(graphics)

Seasonal Holt-Winters
(m <- HoltWinters(co2))
plot(m)
plot(fitted(m))

(m <- HoltWinters(AirPassengers, seasonal = "mult"))
plot(m)

Non-Seasonal Holt-Winters
x <- uspop + rnorm(uspop, sd = 5)
m <- HoltWinters(x, gamma = FALSE)
plot(m)

Exponential Smoothing
m2 <- HoltWinters(x, gamma = FALSE, beta = FALSE)
lines(fitted(m2)[,1], col = 3)
```

**Description**

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

**Usage**

```
dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)
```

### Arguments

|                         |                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls. |
| <code>m</code>          | the number of white balls in the urn.                                                                                                       |
| <code>n</code>          | the number of black balls in the urn.                                                                                                       |
| <code>k</code>          | the number of balls drawn from the urn.                                                                                                     |
| <code>p</code>          | probability, it must be between 0 and 1.                                                                                                    |
| <code>nn</code>         | number of observations. If <code>length(nn) &gt; 1</code> , the length is taken to be the number required.                                  |
| <code>log, log.p</code> | logical; if TRUE, probabilities p are given as log(p).                                                                                      |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                                                       |

### Details

The hypergeometric distribution is used for sampling *without* replacement. The density of this distribution with parameters `m`, `n` and `k` (named  $Np$ ,  $N - Np$ , and  $n$ , respectively in the reference below) is given by

$$p(x) = \binom{m}{x} \binom{n}{k-x} / \binom{m+n}{k}$$

for  $x = 0, \dots, k$ .

The quantile is defined as the smallest value  $x$  such that  $F(x) \geq p$ , where  $F$  is the distribution function.

### Value

`dhyper` gives the density, `phyper` gives the distribution function, `qhyper` gives the quantile function, and `rhyper` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rhyper`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

### Source

`dhyper` computes via binomial probabilities, using code contributed by Catherine Loader (see [dbinom](#)).

`phyper` is based on calculating `dhyper` and `phyper(...)/dhyper(...)` (as a summation), based on ideas of Ian Smith and Morten Welinder.

`qhyper` is based on inversion.

`rhyper` is based on a corrected version of

Kachitvichyanukul, V. and Schmeiser, B. (1985). Computer generation of hypergeometric random variates. *Journal of Statistical Computation and Simulation*, **22**, 127–145.

### References

**See Also**

[Distributions](#) for other standard distributions.

**Examples**

```
m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k))) # FALSE
but error is very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), digits = 3)
```

**identify.hclust**

*Identify Clusters in a Dendrogram*

**Description**

`identify.hclust` reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

**Usage**

```
S3 method for class hclust
identify(x, FUN = NULL, N = 20, MAXCLUSTER = 20, DEV.FUN = NULL,
 ...)
```

**Arguments**

|                         |                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an object of the type produced by <code>hclust</code> .                                                                       |
| <code>FUN</code>        | (optional) function to be applied to the index numbers of the data points in a cluster (see ‘Details’ below).                 |
| <code>N</code>          | the maximum number of clusters to be identified.                                                                              |
| <code>MAXCLUSTER</code> | the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).            |
| <code>DEV.FUN</code>    | (optional) integer scalar. If specified, the corresponding graphics device is made active before <code>FUN</code> is applied. |
| <code>...</code>        | further arguments to <code>FUN</code> .                                                                                       |

**Details**

By default clusters can be identified using the mouse and an `invisible` list of indices of the respective data points is returned.

If `FUN` is not `NULL`, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for `FUN` can be specified using `DEV.FUN`.

The identification process is terminated by pressing any mouse button other than the first, see also [identify](#).

**Value**

Either a list of data point index vectors or a list of return values of FUN.

**See Also**

[hclust](#), [rect.hclust](#)

**Examples**

```
Not run:
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
(x <- identify(hca)) ## Terminate with 2nd mouse button !!

hci <- hclust(dist(iris[,1:4]))
plot(hci)
identify(hci, function(k) print(table(iris[k,5])))

open a new device (one for dendrogram, one for bars):
dev.new() # << make that narrow (& small)
 # and *beside* 1st one
nD <- dev.cur() # to be for the barplot
dev.set(dev.prev()) # old one for dendrogram
plot(hci)
select subtrees in dendrogram and "see" the species distribution:
identify(hci, function(k) barplot(table(iris[k,5]), col = 2:4), DEV.FUN = nD)

End(Not run)
```

**Description**

This suite of functions can be used to compute some of the regression (leave-one-out deletion) diagnostics for linear and generalized linear models discussed in Belsley, Kuh and Welsch (1980), Cook and Weisberg (1982), etc.

**Usage**

```
influence.measures(model)

rstandard(model, ...)
S3 method for class lm
rstandard(model, infl = lm.influence(model, do.coef = FALSE),
 sd = sqrt(deviance(model)/df.residual(model)), ...)
S3 method for class glm
rstandard(model, infl = influence(model, do.coef = FALSE),
 type = c("deviance", "pearson"), ...)

rstudent(model, ...)
```

```

S3 method for class lm
rstudent(model, infl = lm.influence(model, do.coef = FALSE),
 res = infl$wt.res, ...)
S3 method for class glm
rstudent(model, infl = influence(model, do.coef = FALSE), ...)

dffits(model, infl = , res =)

dfbeta(model, ...)
S3 method for class lm
dfbeta(model, infl = lm.influence(model, do.coef = TRUE), ...)

dfbetas(model, ...)
S3 method for class lm
dfbetas(model, infl = lm.influence(model, do.coef = TRUE), ...)

covratio(model, infl = lm.influence(model, do.coef = FALSE),
 res = weighted.residuals(model))

cooks.distance(model, ...)
S3 method for class lm
cooks.distance(model, infl = lm.influence(model, do.coef = FALSE),
 res = weighted.residuals(model),
 sd = sqrt(deviance(model)/df.residual(model)),
 hat = infl$hat, ...)
S3 method for class glm
cooks.distance(model, infl = influence(model, do.coef = FALSE),
 res = infl$pear.res,
 dispersion = summary(model)$dispersion,
 hat = infl$hat, ...)

hatvalues(model, ...)
S3 method for class lm
hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...)

hat(x, intercept = TRUE)

```

## Arguments

|            |                                                                                                                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model      | an R object, typically returned by <code>lm</code> or <code>glm</code> .                                                                                                                            |
| infl       | influence structure as returned by <code>lm.influence</code> or <code>influence</code> (the latter only for the <code>glm</code> method of <code>rstudent</code> and <code>cooks.distance</code> ). |
| res        | (possibly weighted) residuals, with proper default.                                                                                                                                                 |
| sd         | standard deviation to use, see default.                                                                                                                                                             |
| dispersion | dispersion (for <code>glm</code> objects) to use, see default.                                                                                                                                      |
| hat        | hat values $H_{ii}$ , see default.                                                                                                                                                                  |
| type       | type of residuals for <code>glm</code> method for <code>rstandard</code> .                                                                                                                          |
| x          | the $X$ or design matrix.                                                                                                                                                                           |
| intercept  | should an intercept column be prepended to $x$ ?                                                                                                                                                    |
| ...        | further arguments passed to or from other methods.                                                                                                                                                  |

## Details

The primary high-level function is `influence.measures` which produces a class "infl" object tabular display showing the DFBETAS for each model variable, DFFITS, covariance ratios, Cook's distances and the diagonal elements of the hat matrix. Cases which are influential with respect to any of these measures are marked with an asterisk.

The functions `dfbetas`, `dffits`, `covratio` and `cooks.distance` provide direct access to the corresponding diagnostic quantities. Functions `rstandard` and `rstudent` give the standardized and Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using an overall and leave-one-out measure of the error variance respectively.)

Values for generalized linear models are approximations, as described in Williams (1987) (except that Cook's distances are scaled as  $F$  rather than as chi-square values). The approximations can be poor when some cases have large influence.

The optional `infl`, `res` and `sd` arguments are there to encourage the use of these direct access functions, in situations where, e.g., the underlying basic influence measures (from `lm.influence` or the generic `influence`) are already available.

Note that cases with `weights == 0` are *dropped* from all these functions, but that if a linear model has been fitted with `na.action = na.exclude`, suitable values are filled in for the cases excluded during fitting.

The function `hat()` exists mainly for S (version 2) compatibility; we recommend using `hatvalues()` instead.

## Note

For `hatvalues`, `dfbeta`, and `dfbetas`, the method for linear models also works for generalized linear models.

## Author(s)

Several R core team members and John Fox, originally in his 'car' package.

## See Also

`influence` (containing `lm.influence`).

'`plotmath`' for the use of `hat` in plot annotation.

## Examples

```

require(graphics)

Analysis of the life-cycle savings data
given in Belsley, Kuh and Welsch.
lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)

inflm.SR <- influence.measures(lm.SR)
which(apply(inflm.SR$is.inf, 1, any))
which observations are influential
summary(inflm.SR) # only these
inflm.SR # all
plot(rstudent(lm.SR) ~ hatvalues(lm.SR)) # recommended by some

The infl argument is not needed, but avoids recomputation:
rs <- rstandard(lm.SR)
iflSR <- influence(lm.SR)
identical(rs, rstandard(lm.SR, infl = iflSR))
to "see" the larger values:
1000 * round(dfbetas(lm.SR, infl = iflSR), 3)

Hubers data [Atkinson 1985]
xh <- c(-4:0, 10)
yh <- c(2.48, .73, -.04, -1.44, -1.32, 0)
summary(lmH <- lm(yh ~ xh))
(im <- influence.measures(lmH))
plot(xh,yh, main = "Hubers data: L.S. line and influential obs.")
abline(lmH); points(xh[im$is.inf], yh[im$is.inf], pch = 20, col = 2)

Irwins data [Williams 1987]
xi <- 1:5
yi <- c(0,2,14,19,30) # number of mice responding to dose xi
mi <- rep(40, 5) # number of mice exposed
summary(lmI <- glm(cbind(yi, mi - yi) ~ xi, family = binomial))
signif(cooks.distance(lmI), 3) # ~= Ci in Table 3, p.184
(imI <- influence.measures(lmI))
stopifnot(all.equal(imI$infmat[, "cook.d"],
cooks.distance(lmI)))

```

## Description

Adaptive quadrature of functions of one variable over a finite or infinite interval.

## Usage

```

integrate(f, lower, upper, ..., subdivisions = 100L,
 rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol,
 stop.on.error = TRUE, keep.xy = FALSE, aux = NULL)

```

### Arguments

|                                         |                                                                                                                                                           |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>                          | an R function taking a numeric first argument and returning a numeric vector of the same length. Returning a non-finite element will generate an error.   |
| <code>lower</code> , <code>upper</code> | the limits of integration. Can be infinite.                                                                                                               |
| <code>...</code>                        | additional arguments to be passed to <code>f</code> .                                                                                                     |
| <code>subdivisions</code>               | the maximum number of subintervals.                                                                                                                       |
| <code>rel.tol</code>                    | relative accuracy requested.                                                                                                                              |
| <code>abs.tol</code>                    | absolute accuracy requested.                                                                                                                              |
| <code>stop.on.error</code>              | logical. If true (the default) an error stops the function. If false some errors will give a result with a warning in the <code>message</code> component. |
| <code>keep.xy</code>                    | unused. For compatibility with S.                                                                                                                         |
| <code>aux</code>                        | unused. For compatibility with S.                                                                                                                         |

### Details

Note that arguments after `...` must be matched exactly.

If one or both limits are infinite, the infinite range is mapped onto a finite interval.

For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation by Wynn's Epsilon algorithm, with the basic step being Gauss–Kronrod quadrature.

`rel.tol` cannot be less than `max(50 * .Machine$double.eps, 0.5e-28)` if `abs.tol <= 0`.

### Value

A list of class "integrate" with components

|                           |                                                                 |
|---------------------------|-----------------------------------------------------------------|
| <code>value</code>        | the final estimate of the integral.                             |
| <code>abs.error</code>    | estimate of the modulus of the absolute error.                  |
| <code>subdivisions</code> | the number of subintervals produced in the subdivision process. |
| <code>message</code>      | "OK" or a character string giving the error message.            |
| <code>call</code>         | the matched call.                                               |

### Note

Like all numerical integration routines, these evaluate the function on a finite set of points. If the function is approximately constant (in particular, zero) over nearly all its range it is possible that the result and error estimate may be seriously wrong.

When integrating over infinite intervals do so explicitly, rather than just using a large number as the endpoint. This increases the chance of a correct answer – any function whose integral over an infinite interval is finite must be near zero for most of that interval.

For values at a finite set of points to be a fair reflection of the behaviour of the function elsewhere, the function needs to be well-behaved, for example differentiable except perhaps for a small number of jumps or integrable singularities.

`f` must accept a vector of inputs and produce a vector of function evaluations at those points. The [Vectorize](#) function may be helpful to convert `f` to this form.

### Source

Based on QUADPACK routines dqags and dqagi by R. Piessens and E. deDoncker–Kapenga, available from Netlib.

## References

## Examples

```
integrate(dnorm, -1.96, 1.96)
integrate(dnorm, -Inf, Inf)

a slowly-convergent integral
integrand <- function(x) {1/((x+1)*sqrt(x))}

integrate(integrand, lower = 0, upper = Inf)

dont do this if you really want the integral from 0 to Inf
integrate(integrand, lower = 0, upper = 10)
integrate(integrand, lower = 0, upper = 100000)
integrate(integrand, lower = 0, upper = 1000000, stop.on.error = FALSE)

some functions do not handle vector input properly
f <- function(x) 2.0
try(integrate(f, 0, 1))
integrate(Vectorize(f), 0, 1) ## correct
integrate(function(x) rep(2.0, length(x)), 0, 1) ## correct

integrate can fail if misused
integrate(dnorm, 0, 2)
integrate(dnorm, 0, 20)
integrate(dnorm, 0, 200)
integrate(dnorm, 0, 2000)
integrate(dnorm, 0, 20000) ## fails on many systems
integrate(dnorm, 0, Inf) ## works
```

interaction.plot      *Two-way Interaction Plot*

## Description

Plots the mean (or other summary) of the response for two-way combinations of factors, thereby illustrating possible interactions.

## Usage

```
interaction.plot(x.factor, trace.factor, response, fun = mean,
 type = c("l", "p", "b", "o", "c"), legend = TRUE,
 trace.label = deparse(substitute(trace.factor)),
 fixed = FALSE,
 xlab = deparse(substitute(x.factor)),
 ylab = ylabel,
 ylim = range(cells, na.rm = TRUE),
 lty = nc:1, col = 1, pch = c(1:9, 0, letters),
 xpd = NULL, leg.bg = par("bg"), leg.bty = "n",
 xtick = FALSE, xaxt = par("xaxt"), axes = TRUE,
 ...)
```

## Arguments

|                              |                                                                                                                                                                       |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x.factor</code>        | a factor whose levels will form the x axis.                                                                                                                           |
| <code>trace.factor</code>    | another factor whose levels will form the traces.                                                                                                                     |
| <code>response</code>        | a numeric variable giving the response                                                                                                                                |
| <code>fun</code>             | the function to compute the summary. Should return a single real value.                                                                                               |
| <code>type</code>            | the type of plot (see <a href="#">plot.default</a> ): lines or points or both.                                                                                        |
| <code>legend</code>          | logical. Should a legend be included?                                                                                                                                 |
| <code>trace.label</code>     | overall label for the legend.                                                                                                                                         |
| <code>fixed</code>           | logical. Should the legend be in the order of the levels of <code>trace.factor</code> or in the order of the traces at their right-hand ends?                         |
| <code>xlab, ylab</code>      | the x and y label of the plot each with a sensible default.                                                                                                           |
| <code>ylim</code>            | numeric of length 2 giving the y limits for the plot.                                                                                                                 |
| <code>lty</code>             | line type for the lines drawn, with sensible default.                                                                                                                 |
| <code>col</code>             | the color to be used for plotting.                                                                                                                                    |
| <code>pch</code>             | a vector of plotting symbols or characters, with sensible default.                                                                                                    |
| <code>xpd</code>             | determines clipping behaviour for the <a href="#">legend</a> used, see <a href="#">par(xpd)</a> . Per default, the legend is <i>not</i> clipped at the figure border. |
| <code>leg.bg, leg.bty</code> | arguments passed to <a href="#">legend()</a> .                                                                                                                        |
| <code>xtick</code>           | logical. Should tick marks be used on the x axis?                                                                                                                     |
| <code>xaxt, axes, ...</code> | graphics parameters to be passed to the plotting routines.                                                                                                            |

## Details

By default the levels of `x.factor` are plotted on the x axis in their given order, with extra space left at the right for the legend (if specified). If `x.factor` is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting).

The graphics parameters `xlab`, `ylab`, `ylim`, `lty`, `col` and `pch` are given suitable defaults (and `xlim` and `xaxs` are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the capital letters to plot the traces.

## Note

Some of the argument names and the precise behaviour are chosen for S-compatibility.

## Examples

```

require(graphics)

with(ToothGrowth, {
 interaction.plot(dose, supp, len, fixed = TRUE)
 dose <- ordered(dose)
 interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, leg.bty = "o")
 interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, type = "p")
})

with(OrchardSprays, {
 interaction.plot(treatment, rowpos, decrease)
 interaction.plot(rowpos, treatment, decrease, cex.axis = 0.8)
 ## order the rows by their mean effect
 rowpos <- factor(rowpos,
 levels = sort.list(tapply(decrease, rowpos, mean)))
 interaction.plot(rowpos, treatment, decrease, col = 2:9, lty = 1)
})

with(esoph, {
 interaction.plot(agegp, alcgp, ncases/ncontrols, main = "esoph Data")
 interaction.plot(agegp, tobgp, ncases/ncontrols, trace.label = "tobacco",
 fixed = TRUE, xaxt = "n")
})
deal with NAs:
esoph[66,] # second to last age group: 65-74
esophNA <- esoph; esophNA$ncases[66] <- NA
with(esophNA, {
 interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5)
 # doesnt show *last* group either
 interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5, type = "b")
 ## alternative take non-NAs {"cheating"}
 interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5,
 fun = function(x) mean(x, na.rm = TRUE),
 sub = "function(x) mean(x, na.rm=TRUE)")
})
rm(esophNA) # to clear up

```

IQR

*The Interquartile Range*

## Description

computes interquartile range of the *x* values.

## Usage

```
IQR(x, na.rm = FALSE, type = 7)
```

## Arguments

|              |                                                                                          |
|--------------|------------------------------------------------------------------------------------------|
| <i>x</i>     | a numeric vector.                                                                        |
| <i>na.rm</i> | logical. Should missing values be removed?                                               |
| <i>type</i>  | an integer selecting one of the many quantile algorithms, see <a href="#">quantile</a> . |

## Details

Note that this function computes the quartiles using the [quantile](#) function rather than following Tukey's recommendations, i.e.,  $IQR(x) = quantile(x, 3/4) - quantile(x, 1/4)$ .

For normally  $N(m, 1)$  distributed  $X$ , the expected value of  $IQR(X)$  is  $2*qnorm(3/4) = 1.3490$ , i.e., for a normal-consistent estimate of the standard deviation, use  $IQR(x) / 1.349$ .

## Examples

```
IQR(rivers)
```

|                             |                                           |
|-----------------------------|-------------------------------------------|
| <code>is.empty.model</code> | <i>Test if a Model's Formula is Empty</i> |
|-----------------------------|-------------------------------------------|

## Description

R's formula notation allows models with no intercept and no predictors. These require special handling internally. `is.empty.model()` checks whether an object describes an empty model.

## Usage

```
is.empty.model(x)
```

## Arguments

`x` A `terms` object or an object with a `terms` method.

## Value

TRUE if the model is empty

## See Also

[lm](#), [glm](#)

## Examples

```
y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))
```

---

isoreg*Isotonic / Monotone Regression*

---

**Description**

Compute the isotonic (monotonely increasing nonparametric) least squares regression which is piecewise constant.

**Usage**

```
isoreg(x, y = NULL)
```

**Arguments**

|                   |                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code> | coordinate vectors of the regression points. Alternatively a single plotting structure can be specified: see <a href="#">xy.coords</a> . |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------|

**Details**

The algorithm determines the convex minorant  $m(x)$  of the *cumulative* data (i.e., `cumsum(y)`) which is piecewise linear and the result is  $m'(x)$ , a step function with level changes at locations where the convex  $m(x)$  touches the cumulative data polygon and changes slope.

`as.stepfun()` returns a [stepfun](#) object which can be more parsimonious.

**Value**

`isoreg()` returns an object of class `isoreg` which is basically a list with components

|                     |                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | original (constructed) abscissa values <code>x</code> .                                                               |
| <code>y</code>      | corresponding <code>y</code> values.                                                                                  |
| <code>yf</code>     | fitted values corresponding to <i>ordered</i> <code>x</code> values.                                                  |
| <code>yc</code>     | cumulative <code>y</code> values corresponding to <i>ordered</i> <code>x</code> values.                               |
| <code>iKnots</code> | integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks.                |
| <code>is0rd</code>  | logical indicating if original <code>x</code> values were ordered increasingly already.                               |
| <code>ord</code>    | <code>if(!is0rd): integer permutation <a href="#">order</a>(<code>x</code>) of <i>original</i> <code>x</code>.</code> |
| <code>call</code>   | the <code>call</code> to <code>isoreg()</code> used.                                                                  |

**Note**

The code should be improved to accept *weights* additionally and solve the corresponding weighted least squares problem.

'Patches are welcome!'

**See Also**

the plotting method [plot.isoreg](#) with more examples; [isoMDS\(\)](#) from the **MASS** package internally uses isotonic regression.

**Examples**

```
require(graphics)

(ir <- isoreg(c(1,0,4,3,3,5,4,2,0)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,3,5,4,2, 3))) # last "3", not "0"
(fi3 <- as.stepfun(ir3))
(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
cat(sprintf("R^2 = %.2f\n",
 1 - sum(residuals(ir4)^2) / ((10-1)*var(y4)))

If you are interested in the knots alone :
with(ir4, cbind(iKnots, yf[iKnots]))

Example of unordered x[] with ties:
x <- sample((0:30)/8)
y <- exp(x)
x. <- round(x) # ties!
plot(m <- isoreg(x., y))
stopifnot(all.equal(with(m, yf[iKnots]),
 as.vector(tapply(y, x., mean))))
```

**Description**

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

**Usage**

```
KalmanLike(y, mod, nit = 0, fast = TRUE)
KalmanRun(y, mod, nit = 0, fast = TRUE)
KalmanSmooth(y, mod, nit = 0)
KalmanForecast(n.ahead = 10, mod, fast = TRUE)
makeARIMA(phi, theta, Delta, kappa = 1e6)
```

**Arguments**

- |                      |                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>       | a univariate time series.                                                                                                                                                               |
| <code>mod</code>     | A list describing the state-space model: see ‘Details’.                                                                                                                                 |
| <code>nit</code>     | The time at which the initialization is computed. <code>nit = 0</code> implies that the initialization is for a one-step prediction, so $P_n$ should not be computed at the first step. |
| <code>n.ahead</code> | The number of steps ahead for which prediction is required.                                                                                                                             |

|            |                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------|
| phi, theta | numeric vectors of length $\geq 0$ giving AR and MA parameters.                                                  |
| Delta      | vector of differencing coefficients, so an ARMA model is fitted to $y[t] - Delta[1]*y[t-1] - \dots$              |
| kappa      | the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. |
| fast       | If TRUE the mod object may be modified.                                                                          |

### Details

These functions work with a general univariate state-space model with state vector ‘a’, transitions ‘ $a <- T a + R e$ ’,  $e \sim \mathcal{N}(0, \kappa Q)$  and observation equation ‘ $y = Za + \eta$ ’, ( $\eta \equiv \eta_t$ ),  $\eta \sim \mathcal{N}(0, \kappa h)$ . The likelihood is a profile likelihood after estimation of  $\kappa$ .

The model is specified as a list with at least components

T the transition matrix

Z the observation coefficients

h the observation variance

V ‘RQR’

a the current state estimate

P the current estimate of the state uncertainty matrix

Pn the estimate at time  $t - 1$  of the state uncertainty matrix

KalmanSmooth is the workhorse function for [tsSmooth](#).

makeARIMA constructs the state-space model for an ARIMA model.

### Value

For KalmanLike, a list with components Lik (the log-likelihood less some constants) and s2, the estimate of  $\kappa$ .

For KalmanRun, a list with components values, a vector of length 2 giving the output of KalmanLike, resid (the residuals) and states, the contemporaneous state estimates, a matrix with one row for each time.

For KalmanSmooth, a list with two components. Component smooth is a n by p matrix of state estimates based on all the observations, with one row for each time. Component var is a n by p by p array of variance matrices.

For KalmanForecast, a list with components pred, the predictions, and var, the unscaled variances of the prediction errors (to be multiplied by s2).

For makeARIMA, a model list including components for its arguments.

### Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

In particular, KalmanLike alters the objects passed as the elements a, P and Pn of mod, so these should not be shared. Use fast=FALSE to prevent this.

**kernapply**

*Apply Smoothing Kernel*

**Description**

`kernapply` computes the convolution between an input sequence and a specific kernel.

**Usage**

```
kernapply(x, ...)

Default S3 method:
kernapply(x, k, circular = FALSE, ...)
S3 method for class ts
kernapply(x, k, circular = FALSE, ...)
S3 method for class vector
kernapply(x, k, circular = FALSE, ...)

S3 method for class tskernel
kernapply(x, k, ...)
```

**Arguments**

|                       |                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------|
| <code>x</code>        | an input vector, matrix, time series or kernel to be smoothed.                                         |
| <code>k</code>        | smoothing "tskernel" object.                                                                           |
| <code>circular</code> | a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic. |
| <code>...</code>      | arguments passed to or from other methods.                                                             |

**Value**

A smoothed version of the input sequence.

**Note**

This uses [fft](#) to perform the convolution, so is fastest when `NROW(x)` is a power of 2 or some other highly composite integer.

**Author(s)**

A. Trapletti

**Examples**

```
see kernel for examples
```

---

|                     |                                 |
|---------------------|---------------------------------|
| <code>kernel</code> | <i>Smoothing Kernel Objects</i> |
|---------------------|---------------------------------|

---

## Description

The "tskernel" class is designed to represent discrete symmetric normalized smoothing kernels. These kernels can be used to smooth vectors, matrices, or time series objects.

There are `print`, `plot` and `[` methods for these kernel objects.

## Usage

```
kernel(coef, m = 2, r, name)

df.kernel(k)
bandwidth.kernel(k)
is.tskernel(k)

S3 method for class tskernel
plot(x, type = "h", xlab = "k", ylab = "W[k]",
 main = attr(x,"name"), ...)
```

## Arguments

|                                          |                                                                                                                                                                                                                                                                                                  |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>coef</code>                        | the upper half of the smoothing kernel coefficients (including coefficient zero) or the name of a kernel (currently "daniell", "dirichlet", "fejer" or "modified.daniell").                                                                                                                      |
| <code>m</code>                           | the kernel dimension(s) if <code>coef</code> is a name. When <code>m</code> has length larger than one, it means the convolution of kernels of dimension <code>m[j]</code> , for <code>j</code> in <code>1:length(m)</code> . Currently this is supported only for the named "*daniell" kernels. |
| <code>name</code>                        | the name the kernel will be called.                                                                                                                                                                                                                                                              |
| <code>r</code>                           | the kernel order for a Fejer kernel.                                                                                                                                                                                                                                                             |
| <code>k, x</code>                        | a "tskernel" object.                                                                                                                                                                                                                                                                             |
| <code>type, xlab, ylab, main, ...</code> | arguments passed to <code>plot.default</code> .                                                                                                                                                                                                                                                  |

## Details

`kernel` is used to construct a general kernel or named specific kernels. The modified Daniell kernel halves the end coefficients (as used by S-PLUS).

The `[` method allows natural indexing of kernel objects with indices in `(-m) : m`. The normalization is such that for `k <- kernel(*)`, `sum(k[ -k$m : k$m ])` is one.

`df.kernel` returns the 'equivalent degrees of freedom' of a smoothing kernel as defined in Brockwell and Davis (1991), page 362, and `bandwidth.kernel` returns the equivalent bandwidth as defined in Bloomfield (1976), p. 201, with a continuity correction.

## Value

`kernel()` returns an object of class "tskernel" which is basically a list with the two components `coef` and the kernel dimension `m`. An additional attribute is "name".

plot(kernel("fejer", 100, r = 6))
plot(kernel("modified.daniell", c(7,5,3)))

Reproduce example 10.4.3 from Brockwell and Davis (1991)
spectrum(sunspot.year, kernel = kernel("daniell", c(11,7,3)), log = "no")
```

**Description**

Perform k-means clustering on a data matrix.

**Usage**

```
kmeans(x, centers, iter.max = 10, nstart = 1,
 algorithm = c("Hartigan-Wong", "Lloyd", "Forgy",
 "MacQueen"), trace=FALSE)
S3 method for class kmeans
fitted(object, method = c("centers", "classes"), ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).                                                                                       |
| <code>centers</code>   | either the number of clusters, say $k$ , or a set of initial (distinct) cluster centres. If a number, a random set of (distinct) rows in <code>x</code> is chosen as the initial centres.                                            |
| <code>iter.max</code>  | the maximum number of iterations allowed.                                                                                                                                                                                            |
| <code>nstart</code>    | if <code>centers</code> is a number, how many random sets should be chosen?                                                                                                                                                          |
| <code>algorithm</code> | character: may be abbreviated. Note that "Lloyd" and "Forgy" and alternative names for one algorithm.                                                                                                                                |
| <code>object</code>    | an R object of class "kmeans", typically the result ob of <code>ob &lt;- kmeans(..)</code> .                                                                                                                                         |
| <code>method</code>    | character: may be abbreviated. "centers" causes <code>fitted</code> to return cluster centres (one for each input point) and "classes" causes <code>fitted</code> to return a vector of class assignments.                           |
| <code>trace</code>     | logical or integer number, currently only used in the default method ("Hartigan-Wong"): if positive (or true), tracing information on the progress of the algorithm is produced. Higher values may produce more tracing information. |
| <code>...</code>       | not used.                                                                                                                                                                                                                            |

## Details

The data given by `x` are clustered by the  $k$ -means method, which aims to partition the points into  $k$  groups such that the sum of squares from points to the assigned cluster centres is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use  $k$ -means to refer to a specific algorithm rather than the general method: most commonly the algorithm given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The Hartigan–Wong algorithm generally does a better job than either of those, but trying several random starts (`nstart > 1`) is often recommended. In rare cases, when some of the points (rows of `x`) are extremely close, the algorithm may not converge in the "Quick-Transfer" stage, signalling a warning (and returning `ifault = 4`). Slight rounding of the data may be advisable in that case.

For ease of programmatic exploration,  $k = 1$  is allowed, notably returning the center and `withinss`. Except for the Lloyd–Forgy method,  $k$  clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.

## Value

`kmeans` returns an object of class "kmeans" which has a `print` and a `fitted` method. It is a list with at least the following components:

|                           |                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------|
| <code>cluster</code>      | A vector of integers (from 1:k) indicating the cluster to which each point is allocated. |
| <code>centers</code>      | A matrix of cluster centres.                                                             |
| <code>totss</code>        | The total sum of squares.                                                                |
| <code>withinss</code>     | Vector of within-cluster sum of squares, one component per cluster.                      |
| <code>tot.withinss</code> | Total within-cluster sum of squares, i.e., <code>sum(withinss)</code> .                  |

|           |                                                                   |
|-----------|-------------------------------------------------------------------|
| betweenss | The between-cluster sum of squares, i.e. totss-tot.withinss.      |
| size      | The number of points in each cluster.                             |
| iter      | The number of (outer) iterations.                                 |
| ifault    | integer: indicator of a possible algorithm problem – for experts. |

## Examples

```

require(graphics)

a 2-dimensional example
x <- rbind(matrix(rnorm(100, sd = 0.3), ncol = 2),
 matrix(rnorm(100, mean = 1, sd = 0.3), ncol = 2))
colnames(x) <- c("x", "y")
(cl <- kmeans(x, 2))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:2, pch = 8, cex = 2)

sum of squares
ss <- function(x) sum(scale(x, scale = FALSE)^2)

cluster centers "fitted" to each obs.:
fitted.x <- fitted(cl); head(fitted.x)
resid.x <- x - fitted(cl)

Equalities :
cbind(cl[c("betweenss", "tot.withinss", "totss")], # the same two columns
 c(ss(fitted.x), ss(resid.x), ss(x)))
stopifnot(all.equal(cl$totss, ss(x)),
 all.equal(cl$tot.withinss, ss(resid.x)),
 ## these three are the same:
 all.equal(cl$betweenss, ss(fitted.x)),
 all.equal(cl$betweenss, cl$totss - cl$tot.withinss),
 ## and hence also
 all.equal(ss(x), ss(fitted.x) + ss(resid.x))
)

kmeans(x,1)$withinss # trivial one-cluster, (its W.SS == ss(x))

random starts do help here with too many clusters
(and are often recommended anyway!):
(cl <- kmeans(x, 5, nstart = 25))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:5, pch = 8)

```

---

**kruskal.test** *Kruskal-Wallis Rank Sum Test*

---

**Description**

Performs a Kruskal-Wallis rank sum test.

**Usage**

```
kruskal.test(x, ...)

Default S3 method:
kruskal.test(x, g, ...)

S3 method for class formula
kruskal.test(formula, data, subset, na.action, ...)
```

**Arguments**

- |                        |                                                                                                                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a numeric vector of data values, or a list of numeric data vectors.                                                                                                                                                     |
| <code>g</code>         | a vector or factor object giving the group for the corresponding elements of <code>x</code> . Ignored if <code>x</code> is a list.                                                                                      |
| <code>formula</code>   | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.                                                                                |
| <code>data</code>      | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used.                                                                                                                                                      |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                              |
| <code>...</code>       | further arguments to be passed to or from methods.                                                                                                                                                                      |

**Details**

`kruskal.test` performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of `x` are the same in each group (sample). The alternative is that they differ in at least one.

If `x` is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, `g` is ignored, and one can simply use `kruskal.test(x)` to perform the test. If the samples are not yet contained in a list, use `kruskal.test(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

**Value**

A list with class "htest" containing the following components:

- |                        |                                        |
|------------------------|----------------------------------------|
| <code>statistic</code> | the Kruskal-Wallis rank sum statistic. |
|------------------------|----------------------------------------|

|           |                                                                                           |
|-----------|-------------------------------------------------------------------------------------------|
| parameter | the degrees of freedom of the approximate chi-squared distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                  |
| method    | the character string "Kruskal-Wallis rank sum test".                                      |
| data.name | a character string giving the names of the data.                                          |

Mucociliary efficiency from the rate of removal of dust in normal
subjects, subjects with obstructive airway disease, and subjects
with asbestosis.
x <- c(2.9, 3.0, 2.5, 2.6, 3.2) # normal subjects
y <- c(3.8, 2.7, 4.0, 2.4) # with obstructive airway disease
z <- c(2.8, 3.4, 3.7, 2.2, 2.0) # with asbestosis
kruskal.test(list(x, y, z))
Equivalently,
x <- c(x, y, z)
g <- factor(rep(1:3, c(5, 4, 5)),
 labels = c("Normal subjects",
 "Subjects with obstructive airway disease",
 "Subjects with asbestosis"))
kruskal.test(x, g)

Formula interface.
require(graphics)
boxplot(Ozone ~ Month, data = airquality)
kruskal.test(Ozone ~ Month, data = airquality)
```

## Description

Perform a one- or two-sample Kolmogorov-Smirnov test.

**Usage**

```
ks.test(x, y, ...,
 alternative = c("two.sided", "less", "greater"),
 exact = NULL)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | a numeric vector of data values.                                                                                                                                                                                                                               |
| <code>y</code>           | either a numeric vector of data values, or a character string naming a cumulative distribution function or an actual cumulative distribution function such as <code>pnorm</code> . Only continuous CDFs are valid.                                             |
| <code>...</code>         | parameters of the distribution specified (as a character string) by <code>y</code> .                                                                                                                                                                           |
| <code>alternative</code> | indicates the alternative hypothesis and must be one of "two.sided" (default), "less", or "greater". You can specify just the initial letter of the value, but the argument name must be given in full. See 'Details' for the meanings of the possible values. |
| <code>exact</code>       | NULL or a logical indicating whether an exact p-value should be computed. See 'Details' for the meaning of NULL. Not available in the two-sample case for a one-sided test or if ties are present.                                                             |

**Details**

If `y` is numeric, a two-sample test of the null hypothesis that `x` and `y` were drawn from the same *continuous* distribution is performed.

Alternatively, `y` can be a character string naming a continuous (cumulative) distribution function, or such a function. In this case, a one-sample test is carried out of the null that the distribution function which generated `x` is distribution `y` with parameters specified by `...`.

The presence of ties always generates a warning, since continuous distributions do not generate them. If the ties arose from rounding the tests may be approximately valid, but even modest amounts of rounding can have a significant effect on the calculated statistic.

Missing values are silently omitted from `x` and (in the two-sample case) `y`.

The possible values "two.sided", "less" and "greater" of `alternative` specify the null hypothesis that the true distribution function of `x` is equal to, not less than or not greater than the hypothesized distribution function (one-sample case) or the distribution function of `y` (two-sample case), respectively. This is a comparison of cumulative distribution functions, and the test statistic is the maximum difference in value, with the statistic in the "greater" alternative being  $D^+ = \max_u [F_x(u) - F_y(u)]$ . Thus in the two-sample case `alternative = "greater"` includes distributions for which `x` is stochastically *smaller* than `y` (the CDF of `x` lies above and hence to the left of that for `y`), in contrast to `t.test` or `wilcox.test`.

Exact p-values are not available for the two-sample case if one-sided or in the presence of ties. If `exact = NULL` (the default), an exact p-value is computed if the sample size is less than 100 in the one-sample case *and there are no ties*, and if the product of the sample sizes is less than 10000 in the two-sample case. Otherwise, asymptotic distributions are used whose approximations may be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as described in Marsaglia, Tsang & Wang (2003) (but not using the optional approximation in the right tail, so this can be slow for small p-values). The formula of Birnbaum & Tingey (1951) is used for the one-sample one-sided case.

If a single-sample test is used, the parameters specified in `...` must be pre-specified and not estimated from the data. There is some more refined distribution theory for the KS test with estimated parameters (see Durbin, 1973), but that is not implemented in `ks.test`.

**Value**

A list with class "htest" containing the following components:

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>statistic</code>   | the value of the test statistic.                               |
| <code>p.value</code>     | the p-value of the test.                                       |
| <code>alternative</code> | a character string describing the alternative hypothesis.      |
| <code>method</code>      | a character string indicating what type of test was performed. |
| <code>data.name</code>   | a character string giving the name(s) of the data.             |

**Source**

The two-sided one-sample distribution comes *via* Marsaglia, Tsang and Wang (2003).

[shapiro.test](#) which performs the Shapiro-Wilk test for normality.

**Examples**

```
require(graphics)

x <- rnorm(50)
y <- runif(30)
Do x and y come from the same distribution?
ks.test(x, y)
Does x come from a shifted gamma distribution with shape 3 and rate 2?
ks.test(x+2, "pgamma", 3, 2) # two-sided, exact
ks.test(x+2, "pgamma", 3, 2, exact = FALSE)
ks.test(x+2, "pgamma", 3, 2, alternative = "gr")

test if x is stochastically larger than x2
x2 <- rnorm(50, -1)
plot(ecdf(x), xlim = range(c(x, x2)))
plot(ecdf(x2), add = TRUE, lty = "dashed")
t.test(x, x2, alternative = "g")
wilcox.test(x, x2, alternative = "g")
ks.test(x, x2, alternative = "l")
```

---

**ksmooth***Kernel Regression Smoother*

---

**Description**

The Nadaraya–Watson kernel regression estimate.

**Usage**

```
ksmooth(x, y, kernel = c("box", "normal"), bandwidth = 0.5,
 range.x = range(x),
 n.points = max(100L, length(x)), x.points)
```

**Arguments**

|           |                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| x         | input x values. Long vectors are supported.                                                                                                 |
| y         | input y values. Long vectors are supported.                                                                                                 |
| kernel    | the kernel to be used.                                                                                                                      |
| bandwidth | the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at $\pm 0.25 \times \text{bandwidth}$ . |
| range.x   | the range of points to be covered in the output.                                                                                            |
| n.points  | the number of points at which to evaluate the fit.                                                                                          |
| x.points  | points at which to evaluate the smoothed fit. If missing, n.points are chosen uniformly to cover range.x. Long vectors are supported.       |

**Value**

A list with components

|   |                                                                                      |
|---|--------------------------------------------------------------------------------------|
| x | values at which the smoothed fit is evaluated. Guaranteed to be in increasing order. |
| y | fitted values corresponding to x.                                                    |

**Note**

This function was implemented for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages such as **KernSmooth**.

**Examples**

```
require(graphics)

with(cars, {
 plot(speed, dist)
 lines(ksmooth(speed, dist, "normal", bandwidth = 2), col = 2)
 lines(ksmooth(speed, dist, "normal", bandwidth = 5), col = 3)
})
```

---

**lag***Lag a Time Series*

---

**Description**

Compute a lagged version of a time series, shifting the time base back by a given number of observations.

**Usage**

```
lag(x, ...)
Default S3 method:
lag(x, k = 1, ...)
```

**Arguments**

|     |                                                              |
|-----|--------------------------------------------------------------|
| x   | A vector or matrix or univariate or multivariate time series |
| k   | The number of lags (in units of observations).               |
| ... | further arguments to be passed to or from methods.           |

**Details**

Vector or matrix arguments x are coerced to time series.

lag is a generic function; this page documents its default method.

**Value**

A time series object.

**Note**

Note the sign of k: a series lagged by a positive k starts *earlier*.

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**

[diff](#), [deltat](#)

**Examples**

```
lag(ldeaths, 12) # starts one year earlier
```

---

**lag.plot***Time Series Lag Plots*

---

**Description**

Plot time series against lagged versions of themselves. Helps visualizing ‘auto-dependence’ even when auto-correlations vanish.

**Usage**

```
lag.plot(x, lags = 1, layout = NULL, set.lags = 1:lags,
 main = NULL, asp = 1,
 diag = TRUE, diag.col = "gray", type = "p", oma = NULL,
 ask = NULL, do.lines = (n <= 150), labels = do.lines,
 ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | time-series (univariate or multivariate)                                                                                                                                                                                                                                                                                                    |
| <code>lags</code>     | number of lag plots desired, see arg <code>set.lags</code> .                                                                                                                                                                                                                                                                                |
| <code>layout</code>   | the layout of multiple plots, basically the <code>mfrow</code> <code>par()</code> argument. The default uses about a square layout (see <code>n2mfrow</code> such that all plots are on one page).                                                                                                                                          |
| <code>set.lags</code> | vector of positive integers allowing specification of the set of lags used; defaults to <code>1:lags</code> .                                                                                                                                                                                                                               |
| <code>main</code>     | character with a main header title to be done on the top of each page.                                                                                                                                                                                                                                                                      |
| <code>asp</code>      | Aspect ratio to be fixed, see <code>plot.default</code> .                                                                                                                                                                                                                                                                                   |
| <code>diag</code>     | logical indicating if the <code>x=y</code> diagonal should be drawn.                                                                                                                                                                                                                                                                        |
| <code>diag.col</code> | color to be used for the diagonal <code>if(diag)</code> .                                                                                                                                                                                                                                                                                   |
| <code>type</code>     | plot type to be used, but see <code>plot.ts</code> about its restricted meaning.                                                                                                                                                                                                                                                            |
| <code>oma</code>      | outer margins, see <code>par</code> .                                                                                                                                                                                                                                                                                                       |
| <code>ask</code>      | logical or <code>NULL</code> ; if true, the user is asked to confirm before a new page is started.                                                                                                                                                                                                                                          |
| <code>do.lines</code> | logical indicating if lines should be drawn.                                                                                                                                                                                                                                                                                                |
| <code>labels</code>   | logical indicating if labels should be used.                                                                                                                                                                                                                                                                                                |
| <code>...</code>      | Further arguments to <code>plot.ts</code> . Several graphical parameters are set in this function and so cannot be changed: these include <code>xlab</code> , <code>ylab</code> , <code>mgp</code> , <code>col.lab</code> and <code>font.lab</code> : this also applies to the arguments <code>xy.labels</code> and <code>xy.lines</code> . |

**Details**

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced, `par(mfrow)` and several other graphics parameters will be set, so it is not (easily) possible to mix such lag plots with other plots on the same page.

If `ask = NULL`, `par(ask = TRUE)` will be called if more than one page of plots is to be produced and the device is interactive.

**Note**

It is more flexible and has different default behaviour than the S version. We use `main =` instead of `head =` for internal consistency.

**Author(s)**

Martin Maechler

**See Also**

[plot.ts](#) which is the basic work horse.

**Examples**

```
require(graphics)

lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main = "Average Temperatures in New Haven")
ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
 main = "New Haven Temperatures", col.main = "blue")

Multivariate (but non-stationary! ...)
lag.plot(freeny.x, lags = 3)
Not run:
no lines for long series :
lag.plot(sqrt(sunspots), set = c(1:4, 9:12), pch = ".", col = "gold")

End(Not run)
```

**line**

*Robust Line Fitting*

**Description**

Fit a line robustly as recommended in *Exploratory Data Analysis*.

**Usage**

```
line(x, y)
```

**Arguments**

`x, y` the arguments can be any way of specifying x-y pairs. See [xy.coords](#).

**Details**

Cases with missing values are omitted.

Long vectors are not supported.

## Value

An object of class "tukeyline".

Methods are available for the generic functions `coef`, `residuals`, `fitted`, and `print`.

## References

Tukey, J. W. (1977). *Exploratory Data Analysis*, Reading Massachusetts: Addison-Wesley.

## See Also

[lm](#).

## Examples

```
require(graphics)

plot(cars)
(z <- line(cars))
abline(coef(z))
Tukey-Anscombe Plot :
plot(residuals(z) ~ fitted(z), main = deparse(z$call))
```

## Description

`lm` is used to fit linear models. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although `aov` may provide a more convenient interface for these).

## Usage

```
lm(formula, data, subset, weights, na.action,
 method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE,
 singular.ok = TRUE, contrasts = NULL, offset, ...)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code> | an object of class " <a href="#">formula</a> " (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.                                                                                                                  |
| <code>data</code>    | an optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>lm</code> is called. |
| <code>subset</code>  | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                   |

|                              |                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>weights</code>         | an optional vector of weights to be used in the fitting process. Should be <code>NULL</code> or a numeric vector. If non- <code>NULL</code> , weighted least squares is used with weights <code>weights</code> (that is, minimizing <code>sum(w*e^2)</code> ); otherwise ordinary least squares is used. See also ‘Details’,                                                                      |
| <code>na.action</code>       | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . Another possible value is <code>NULL</code> , no action. Value <code>na.exclude</code> can be useful.                             |
| <code>method</code>          | the method to be used; for fitting, currently only <code>method = "qr"</code> is supported; <code>method = "model.frame"</code> returns the model frame (the same as with <code>model = TRUE</code> , see below).                                                                                                                                                                                 |
| <code>model, x, y, qr</code> | logicals. If <code>TRUE</code> the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.                                                                                                                                                                                                                                      |
| <code>singular.ok</code>     | logical. If <code>FALSE</code> (the default in S but not in R) a singular fit is an error.                                                                                                                                                                                                                                                                                                        |
| <code>contrasts</code>       | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                                                                                                                                                                                                                                                                       |
| <code>offset</code>          | this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be <code>NULL</code> or a numeric vector of length equal to the number of cases. One or more <code>offset</code> terms can be included in the formula instead or as well, and if more than one are specified their sum is used. See <code>model.offset</code> . |
| <code>...</code>             | additional arguments to be passed to the low level regression fitting functions (see below).                                                                                                                                                                                                                                                                                                      |

## Details

Models for `lm` are specified symbolically. A typical model has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for `response`. A `terms` specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with duplicates removed. A specification of the form `first:second` indicates the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the *cross* of `first` and `second`. This is the same as `first + second + first:second`.

If the formula includes an `offset`, this is evaluated and subtracted from the response.

If `response` is a matrix a linear model is fitted separately by least-squares to each column of the matrix.

See `model.matrix` for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a `terms` object as the formula (see `aov` and `demo(glm.vr)` for an example).

A formula has an implied intercept term. To remove this use either `y ~ x - 1` or `y ~ 0 + x`. See `formula` for more details of allowed formulae.

Non-`NULL` `weights` can be used to indicate that different observations have different variances (with the values in `weights` being inversely proportional to the variances); or equivalently, when the elements of `weights` are positive integers  $w_i$ , that each response  $y_i$  is the mean of  $w_i$  unit-weight observations (including the case that there are  $w_i$  observations equal to  $y_i$  and the data have been summarized).

`lm` calls the lower level functions `lm.fit`, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of `weights`, `subset` and `offset` are evaluated in the same way as variables in `formula`, that is first in `data` and then in the environment of `formula`.

### Value

`lm` returns an object of `class "lm"` or for multiple responses of class `c("m1m", "lm")`.

The functions `summary` and `anova` are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` extract various useful features of the value returned by `lm`.

An object of class "`lm`" is a list containing at least the following components:

|                            |                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------|
| <code>coefficients</code>  | a named vector of coefficients                                                                    |
| <code>residuals</code>     | the residuals, that is response minus fitted values.                                              |
| <code>fitted.values</code> | the fitted mean values.                                                                           |
| <code>rank</code>          | the numeric rank of the fitted linear model.                                                      |
| <code>weights</code>       | (only for weighted fits) the specified weights.                                                   |
| <code>df.residual</code>   | the residual degrees of freedom.                                                                  |
| <code>call</code>          | the matched call.                                                                                 |
| <code>terms</code>         | the <code>terms</code> object used.                                                               |
| <code>contrasts</code>     | (only where relevant) the contrasts used.                                                         |
| <code>xlevels</code>       | (only where relevant) a record of the levels of the factors used in fitting.                      |
| <code>offset</code>        | the offset used (missing if none were used).                                                      |
| <code>y</code>             | if requested, the response used.                                                                  |
| <code>x</code>             | if requested, the model matrix used.                                                              |
| <code>model</code>         | if requested (the default), the model frame used.                                                 |
| <code>na.action</code>     | (where relevant) information returned by <code>model.frame</code> on the special handling of NAs. |

In addition, non-null fits will have components `assign`, `effects` and (unless not requested) `qr` relating to the linear fit, for use by extractor functions such as `summary` and `effects`.

### Using time series

Considerable care is needed when using `lm` with time series.

Unless `na.action = NULL`, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by `ts.intersect(..., dframe = TRUE)`, then apply a suitable `na.action` to that data frame and call `lm` with `na.action = NULL` so that residuals and fitted values are time series.

### Note

Offsets specified by `offset` will not be included in predictions by `predict.lm`, whereas those specified by an offset term in the formula will be.

### Author(s)

The design was inspired by the `S` function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

```

## Description

These are the basic computing engines called by `lm` used to fit linear models. These should usually *not* be used directly unless by experienced users.

**Usage**

```
lm.fit (x, y, offset = NULL, method = "qr", tol = 1e-7,
 singular.ok = TRUE, ...)
```

```
lm.wfit(x, y, w, offset = NULL, method = "qr", tol = 1e-7,
 singular.ok = TRUE, ...)
```

**Arguments**

|             |                                                                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | design matrix of dimension n * p.                                                                                                                                      |
| y           | vector of observations of length n, or a matrix with n rows.                                                                                                           |
| w           | vector of weights (length n) to be used in the fitting process for the wfit functions. Weighted least squares is used with weights w, i.e., sum(w * e^2) is minimized. |
| offset      | numeric of length n). This can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting.                            |
| method      | currently, only method = "qr" is supported.                                                                                                                            |
| tol         | tolerance for the qr decomposition. Default is 1e-7.                                                                                                                   |
| singular.ok | logical. If FALSE, a singular model is an error.                                                                                                                       |
| ...         | currently disregarded.                                                                                                                                                 |

**Value**

a list with components

|               |                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| coefficients  | p vector                                                                                                                                           |
| residuals     | n vector or matrix                                                                                                                                 |
| fitted.values | n vector or matrix                                                                                                                                 |
| effects       | (not null fits)n vector of orthogonal single-df effects. The first rank of them correspond to non-aliased coefficients, and are named accordingly. |
| weights       | n vector — <i>only</i> for the *wfit* functions.                                                                                                   |
| rank          | integer, giving the rank                                                                                                                           |
| df.residual   | degrees of freedom of residuals                                                                                                                    |
| qr            | (not null fits) the QR decomposition, see qr.                                                                                                      |

**See Also**

[lm](#) which you should use for linear least squares regression, unless you know better.

**Examples**

```
require(utils)

set.seed(129)
n <- 7 ; p <- 2
X <- matrix(rnorm(n * p), n, p) # no intercept!
y <- rnorm(n)
w <- rnorm(n)^2

str(lmw <- lm.wfit(x = X, y = y, w = w))
```

```
str(lm. <- lm.fit (x = X, y = y))
```

**lm.influence***Regression Diagnostics***Description**

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.

**Usage**

```
influence(model, ...)
S3 method for class lm
influence(model, do.coef = TRUE, ...)
S3 method for class glm
influence(model, do.coef = TRUE, ...)

lm.influence(model, do.coef = TRUE)
```

**Arguments**

- |                      |                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------|
| <code>model</code>   | an object as returned by <code>lm</code> or <code>glm</code> .                                                |
| <code>do.coef</code> | logical indicating if the changed coefficients (see below) are desired. These need $O(n^2 p)$ computing time. |
| <code>...</code>     | further arguments passed to or from other methods.                                                            |

**Details**

The `influence.measures()` and other functions listed in **See Also** provide a more user oriented way of computing a variety of regression diagnostics. These all build on `lm.influence`. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.

An attempt is made to ensure that computed hat values that are probably one are treated as one, and the corresponding rows in `sigma` and `coefficients` are NaN. (Dropping such a case would normally result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.)

`naresid` is applied to the results and so will fill in with NAs if the fit had `na.action = na.exclude`.

**Value**

A list containing the following components of the same length or number of rows  $n$ , which is the number of non-zero weights. Cases omitted in the fit are omitted unless a `na.action` method was used (such as `na.exclude`) which restores them.

- |                           |                                                                                                                                                                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>hat</code>          | a vector containing the diagonal of the ‘hat’ matrix.                                                                                                                                                                                                  |
| <code>coefficients</code> | (unless <code>do.coef</code> is false) a matrix whose $i$ -th row contains the change in the estimated coefficients which results when the $i$ -th case is dropped from the regression. Note that aliased coefficients are not included in the matrix. |

|        |                                                                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sigma  | a vector whose i-th element contains the estimate of the residual standard deviation obtained when the i-th case is dropped from the regression. (The approximations needed for GLMs can result in this being NaN.) |
| wt.res | a vector of <i>weighted</i> (or for class <code>glm</code> rather <i>deviance</i> ) residuals.                                                                                                                      |

### Note

The coefficients returned by the R version of `lm.influence` differ from those computed by S. Rather than returning the coefficients which result from dropping each case, we return the changes in the coefficients. This is more directly useful in many diagnostic measures.

Since these need  $O(n^2 p)$  computing time, they can be omitted by `do.coef = FALSE`.

Note that cases with `weights == 0` are *dropped* (contrary to the situation in S).

If a model has been fitted with `na.action = na.exclude` (see [na.exclude](#)), cases excluded in the fit *are* considered here.

```

### Description

All these functions are [methods](#) for class "lm" objects.

## Usage

```
S3 method for class lm
family(object, ...)

S3 method for class lm
formula(x, ...)

S3 method for class lm
residuals(object,
 type = c("working", "response", "deviance", "pearson",
 "partial"),
 ...)

S3 method for class lm
labels(object, ...)
```

## Arguments

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>object, x</code> | an object inheriting from class <code>lm</code> , usually the result of a call to <code>lm</code> or <code>aov</code> . |
| <code>...</code>       | further arguments passed to or from other methods.                                                                      |
| <code>type</code>      | the type of residuals which should be returned.                                                                         |

## Details

The generic accessor functions `coef`, `effects`, `fitted` and `residuals` can be used to extract various useful features of the value returned by `lm`.

The working and response residuals are ‘observed - fitted’. The deviance and pearson residuals are weighted residuals, scaled by the square root of the weights used in fitting. The partial residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized `rstudent` residuals, and the `weighted.residuals`).

How `residuals` treats cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear, with residual value NA. See also `naresid`.

The “`lm`” method for generic `labels` returns the term labels for estimable terms, that is the names of the terms with at least one estimable coefficient.

`coef`, `deviance`, `df.residual`, `effects`, `fitted`, `glm` for **generalized** linear models, `influence` (etc on that page) for regression diagnostics, `weighted.residuals`, `residuals`, `residuals.glm`, `summary.lm`, `weights`.

`influence.measures` for deletion diagnostics, including standardized (`rstandard`) and studentized (`rstudent`) residuals.

## Examples

```
##-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients

The 2 basic regression diagnostic plots [plot.lm(.) is preferred]
plot(resid(lm.D90), fitted(lm.D90)) # Tukey-Anscombes
abline(h = 0, lty = 2, col = "gray")

qqnorm(residuals(lm.D90))
```

loadings

*Print Loadings in Factor Analysis*

## Description

Extract or print loadings in factor analysis (or principal components analysis).

## Usage

```
loadings(x)

S3 method for class loadings
print(x, digits = 3, cutoff = 0.1, sort = FALSE, ...)

S3 method for class factanal
print(x, digits = 3, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | an object of class " <a href="#">factanal</a> " or " <a href="#">princomp</a> " or the <code>loadings</code> component of such an object.                                                                                                                                                            |
| <code>digits</code> | number of decimal places to use in printing uniquenesses and loadings.                                                                                                                                                                                                                               |
| <code>cutoff</code> | loadings smaller than this (in absolute value) are suppressed.                                                                                                                                                                                                                                       |
| <code>sort</code>   | logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned. |
| <code>...</code>    | further arguments for other methods.                                                                                                                                                                                                                                                                 |

## Details

'Loadings' is a term from *factor analysis*, but because factor analysis and principal component analysis (PCA) are often conflated in the social science literature, it was used for PCA by SPSS and hence by [princomp](#) in S-PLUS to help SPSS users.

Small loadings are conventionally not printed (replaced by spaces), to draw the eye to the pattern of the larger loadings.

The `print` method for class "[factanal](#)" calls the "`loadings`" method to print the loadings, and so passes down arguments such as `cutoff` and `sort`.

loess

*Local Polynomial Regression Fitting*

**Description**

Fit a polynomial surface determined by one or more numerical predictors, using local fitting.

**Usage**

```
loess(formula, data, weights, subset, na.action, model = FALSE,
 span = 0.75, enp.target, degree = 2,
 parametric = FALSE, drop.square = FALSE, normalize = TRUE,
 family = c("gaussian", "symmetric"),
 method = c("loess", "model.frame"),
 control = loess.control(...), ...)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula     | a <a href="#">formula</a> specifying the numeric response and one to four numeric predictors (best specified via an interaction, but can also be specified additively). Will be coerced to a formula if necessary.                                                                                        |
| data        | an optional data frame, list or environment (or object coercible by <a href="#">as.data.frame</a> to a data frame) containing the variables in the model. If not found in data, the variables are taken from <a href="#">environment(formula)</a> , typically the environment from which loess is called. |
| weights     | optional weights for each case.                                                                                                                                                                                                                                                                           |
| subset      | an optional specification of a subset of the data to be used.                                                                                                                                                                                                                                             |
| na.action   | the action to be taken with missing values in the response or predictors. The default is given by <a href="#">getOption("na.action")</a> .                                                                                                                                                                |
| model       | should the model frame be returned?                                                                                                                                                                                                                                                                       |
| span        | the parameter $\alpha$ which controls the degree of smoothing.                                                                                                                                                                                                                                            |
| enp.target  | an alternative way to specify span, as the approximate equivalent number of parameters to be used.                                                                                                                                                                                                        |
| degree      | the degree of the polynomials to be used, normally 1 or 2. (Degree 0 is also allowed, but see the 'Note'.)                                                                                                                                                                                                |
| parametric  | should any terms be fitted globally rather than locally? Terms can be specified by name, number or as a logical vector of the same length as the number of predictors.                                                                                                                                    |
| drop.square | for fits with more than one predictor and <code>degree = 2</code> , should the quadratic term be dropped for particular predictors? Terms are specified in the same way as for <code>parametric</code> .                                                                                                  |
| normalize   | should the predictors be normalized to a common scale if there is more than one? The normalization used is to set the 10% trimmed standard deviation to one. Set to false for spatial coordinate predictors and others known to be a common scale.                                                        |

|         |                                                                                                                                   |
|---------|-----------------------------------------------------------------------------------------------------------------------------------|
| family  | if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M estimator is used with Tukey's biweight function. |
| method  | fit the model or just extract the model frame.                                                                                    |
| control | control parameters: see <a href="#">loess.control</a> .                                                                           |
| ...     | control parameters can also be supplied directly.                                                                                 |

## Details

Fitting is done locally. That is, for the fit at point  $x$ , the fit is made using points in a neighbourhood of  $x$ , weighted by their distance from  $x$  (with differences in 'parametric' variables being ignored when computing the distance). The size of the neighbourhood is controlled by  $\alpha$  (set by `span` or `enp.target`). For  $\alpha < 1$ , the neighbourhood includes proportion  $\alpha$  of the points, and these have tricubic weighting (proportional to  $(1 - (\text{dist}/\text{maxdist})^3)^3$ ). For  $\alpha > 1$ , all points are used, with the 'maximum distance' assumed to be  $\alpha^{1/p}$  times the actual maximum distance for  $p$  explanatory variables.

For the default family, fitting is by (weighted) least squares. For `family="symmetric"` a few iterations of an M-estimation procedure with Tukey's biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See [loess.control](#) for details.

## Value

An object of class "loess".

## Note

As this is based on `cloess`, it is similar to but not identical to the `loess` function of S. In particular, conditioning is not implemented.

The memory usage of this implementation of `loess` is roughly quadratic in the number of points, with 1000 points taking about 10Mb.

`degree = 0`, local constant fitting, is allowed in this implementation but not documented in the reference. It seems very little tested, so use with caution.

## Author(s)

B. D. Ripley, based on the `cloess` package of Cleveland, Grosse and Shyu.

## Source

The 1998 version of `cloess` package of Cleveland, Grosse and Shyu. A later version is available as `dloess` at <http://www.netlib.org/a>.

## References

## See Also

[loess.control](#), [predict.loess](#).

[lowess](#), the ancestor of `loess` (with different defaults!).

## Examples

```

cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
to allow extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)

```

**loess.control**

*Set Parameters for Loess*

## Description

Set control parameters for loess fits.

## Usage

```
loess.control(surface = c("interpolate", "direct"),
 statistics = c("approximate", "exact"),
 trace.hat = c("exact", "approximate"),
 cell = 0.2, iterations = 4, ...)
```

## Arguments

|                         |                                                                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>surface</code>    | should the fitted surface be computed exactly or via interpolation from a kd tree?                                                                                                                              |
| <code>statistics</code> | should the statistics be computed exactly or approximately? Exact computation can be very slow.                                                                                                                 |
| <code>trace.hat</code>  | should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points.                                                  |
| <code>cell</code>       | if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the kd tree. Cells with more than <code>floor(n*span*cell)</code> points are subdivided. |
| <code>iterations</code> | the number of iterations used in robust fitting.                                                                                                                                                                |
| <code>...</code>        | further arguments which are ignored.                                                                                                                                                                            |

## Value

A list with components

`surface`  
`statistics`  
`trace.hat`  
`cell`  
`iterations`

with meanings as explained under ‘Arguments’.

[loess](#)

---

Logistic*The Logistic Distribution*

---

**Description**

Density, distribution function, quantile function and random generation for the logistic distribution with parameters `location` and `scale`.

**Usage**

```
dlogis(x, location = 0, scale = 1, log = FALSE)
plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rlogis(n, location = 0, scale = 1)
```

**Arguments**

|                              |                                                                                                           |
|------------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>            | vector of quantiles.                                                                                      |
| <code>p</code>               | vector of probabilities.                                                                                  |
| <code>n</code>               | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>location, scale</code> | location and scale parameters.                                                                            |
| <code>log, log.p</code>      | logical; if TRUE, probabilities p are given as log(p).                                                    |
| <code>lower.tail</code>      | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

If `location` or `scale` are omitted, they assume the default values of 0 and 1 respectively.

The Logistic distribution with `location =  $\mu$`  and `scale =  $\sigma$`  has distribution function

$$F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}$$

and density

$$f(x) = \frac{1}{\sigma} \frac{e^{(x-\mu)/\sigma}}{(1 + e^{(x-\mu)/\sigma})^2}$$

It is a long-tailed distribution with mean  $\mu$  and variance  $\pi^2/3\sigma^2$ .

**Value**

`dlogis` gives the density, `plogis` gives the distribution function, `qlogis` gives the quantile function, and `rlogis` generates random deviates.

The length of the result is determined by `n` for `rlogis`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Note**

`qlogis(p)` is the same as the well known ‘*logit*’ function,  $\text{logit}(p) = \log p / (1-p)$ , and `plogis(x)` has consequently been called the ‘inverse logit’.

The distribution function is a rescaled hyperbolic tangent, `plogis(x) == (1+ tanh(x/2))/2`, and it is called a *sigmoid function* in contexts such as neural networks.

**Source**

[dpq]logis are calculated directly from the definitions.

rlogis uses inversion.

**See Also**

[Distributions](#) for other standard distributions.

**Examples**

```
var(rlogis(4000, 0, scale = 5)) # approximately (+/- 3)
pi^2/3 * 5^2
```

**logLik**

*Extract Log-Likelihood*

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which have methods for this function include: "glm", "lm", "nls" and "Arima". Packages contain methods for other classes, such as "fitdistr", "negbin" and "polr" in package **MASS**, "multinom" in package **nnet** and "gls", "gnls" "lme" and others in package **nlme**.

**Usage**

```
logLik(object, ...)
S3 method for class lm
logLik(object, REML = FALSE, ...)
```

**Arguments**

- |        |                                                                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| object | any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.                                     |
| ...    | some methods for this generic function require additional arguments.                                                                             |
| REML   | an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE. |

## Details

`logLik` is most commonly used for a model fitted by maximum likelihood, and some uses, e.g. by [AIC](#), assume this. So care is needed where other fit criteria have been used, for example REML (the default for "lme").

For a "glm" fit the [family](#) does not have to specify how to calculate the log-likelihood, so this is based on using the family's `aic()` function to compute the AIC. For the [gaussian](#), [Gamma](#) and [inverse.gaussian](#) families it assumed that the dispersion of the GLM is estimated and has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known. Note that this procedure does not give the maximized likelihood for "glm" fits from the Gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included. That method is only applicable to single-response fits.

## Value

Returns an object of class `logLik`. This is a number with at least one attribute, "df" (degrees of freedom), giving the number of (estimated) parameters in the model.

There is a simple print method for "logLik" objects.

There may be other attributes depending on the method used: see the appropriate documentation. One that is used by several methods is "nobs", the number of observations used in estimation (after the restrictions if `REML = TRUE`).

## Examples

```
x <- 1:5
lmx <- lm(x ~ 1)
logLik(lmx) # using print.logLik() method
utils::str(logLik(lmx))

lm method
(fm1 <- lm(rating ~ ., data = attitude))
logLik(fm1)
logLik(fm1, REML = TRUE)

utils::data(Orthodont, package = "nlme")
fm1 <- lm(distance ~ Sex * age, Orthodont)
```

```
logLik(fm1)
logLik(fm1, REML = TRUE)
```

**loglin***Fitting Log-Linear Models***Description**

`loglin` is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

**Usage**

```
loglin(table, margin, start = rep(1, length(table)), fit = FALSE,
 eps = 0.1, iter = 20, param = FALSE, print = TRUE)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>table</code>  | a contingency table to be fit, typically the output from <code>table</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>margin</code> | a list of vectors with the marginal totals to be fit.<br>(Hierarchical) log-linear models can be specified in terms of these marginal totals which give the ‘maximal’ factor subsets contained in the model. For example, in a three-factor model, <code>list(c(1, 2), c(1, 3))</code> specifies a model which contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as ‘[12][13]’).<br>The names of factors (i.e., <code>names(dimnames(table))</code> ) may be used rather than numeric indices. |
| <code>start</code>  | a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in <code>table</code> which should be preserved in the fit. In this case, the corresponding entries in <code>start</code> should be zero and the others can be taken as one.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>fit</code>    | a logical indicating whether the fitted values should be returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>eps</code>    | maximum deviation allowed between observed and fitted margins.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>iter</code>   | maximum number of iterations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>param</code>  | a logical indicating whether the parameter values should be returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>print</code>  | a logical. If <code>TRUE</code> , the number of iterations and the final deviation are printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Details**

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most `iter` iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than `eps`. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with `df` degrees of freedom.

Note that the IPF steps are applied to the factors in the order given in `margin`. Hence if the model is decomposable and the order given in `margin` is a running intersection property ordering then IPF will converge in one iteration.

Package **MASS** contains `loglm`, a front-end to `loglin` which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as `lm` or `glm`.

### Value

A list with the following components.

|                      |                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lrt</code>     | the Likelihood Ratio Test statistic.                                                                                                                                                                                             |
| <code>pearson</code> | the Pearson test statistic (X-squared).                                                                                                                                                                                          |
| <code>df</code>      | the degrees of freedom for the fitted model. There is no adjustment for structural zeros.                                                                                                                                        |
| <code>margin</code>  | list of the margins that were fit. Basically the same as the input <code>margin</code> , but with numbers replaced by names where possible.                                                                                      |
| <code>fit</code>     | An array like <code>table</code> containing the fitted values. Only returned if <code>fit</code> is TRUE.                                                                                                                        |
| <code>param</code>   | A list containing the estimated parameters of the model. The ‘standard’ constraints of zero marginal sums (e.g., zero row and column sums for a two factor parameter) are employed. Only returned if <code>param</code> is TRUE. |

**Lognormal***The Log Normal Distribution***Description**

Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to `meanlog` and standard deviation equal to `sdlog`.

**Usage**

```
dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)
plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
rlnorm(n, meanlog = 0, sdlog = 1)
```

**Arguments**

|                             |                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>x, q</code>           | vector of quantiles.                                                                                          |
| <code>p</code>              | vector of probabilities.                                                                                      |
| <code>n</code>              | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required.     |
| <code>meanlog, sdlog</code> | mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively. |
| <code>log, log.p</code>     | logical; if TRUE, probabilities p are given as log(p).                                                        |
| <code>lower.tail</code>     | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                         |

**Details**

The log normal distribution has density

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma x} e^{-(\log(x)-\mu)^2/2\sigma^2}$$

where  $\mu$  and  $\sigma$  are the mean and standard deviation of the logarithm. The mean is  $E(X) = \exp(\mu + 1/2\sigma^2)$ , the median is  $\text{med}(X) = \exp(\mu)$ , and the variance  $\text{Var}(X) = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)$  and hence the coefficient of variation is  $\sqrt{\exp(\sigma^2) - 1}$  which is approximately  $\sigma$  when that is small (e.g.,  $\sigma < 1/2$ ).

**Value**

`dlnorm` gives the density, `plnorm` gives the distribution function, `qlnorm` gives the quantile function, and `rlnorm` generates random deviates.

The length of the result is determined by `n` for `rlnorm`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Note**

The cumulative hazard  $H(t) = -\log(1-F(t))$  is `-plnorm(t, r, lower = FALSE, log = TRUE)`.

## Source

`dlnorm` is calculated from the definition (in ‘Details’). `[pqr]lnorm` are based on the relationship to the normal.

## Description

This function performs the computations for the *LOWESS* smoother which uses locally-weighted polynomial regression (see the references).

## Usage

```
lowess(x, y = NULL, f = 2/3, iter = 3, delta = 0.01 * diff(range(x)))
```

## Arguments

- `x, y` vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified – see [xy.coords](#).
- `f` the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.
- `iter` the number of ‘robustifying’ iterations which should be performed. Using smaller values of `iter` will make `lowess` run faster.
- `delta` See ‘Details’. Defaults to 1/100th of the range of `x`.

## Details

`lowess` is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file ‘src/app1/lowess.doc’. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the  $\text{f} \times n$ th nearest neighbour, and tricubic weighting is used for `x` which fall within the neighbourhood.

The initial fit is done using weighted least squares. If `iter > 0`, further weighted fits are done using the product of the weights from the proximity of the `x` values and case weights derived from the

residuals at the previous iteration. Specifically, the case weight is Tukey's biweight, with cutoff 6 times the MAD of the residuals. (The current R implementation differs from the original in stopping iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

`delta` is used to speed up computation: instead of computing the local polynomial fit at each data point it is not computed for points within `delta` of the last computed point, and linear interpolation is used to fill in the fitted values for the skipped points.

### Value

`lowess` returns a list containing components `x` and `y` which give the coordinates of the smooth. The smooth can be added to a plot of the original points with the function `lines`: see the examples.

[loess](#), a newer formula based version of `lowess` (with different defaults!).

### Examples

```
require(graphics)

plot(cars, main = "lowess(cars)")
lines(lowess(cars), col = 2)
lines(lowess(cars, f = .2), col = 3)
legend(5, 120, c(paste("f = ", c(".2/", ".2"))), lty = 1, col = 2:3)
```

## ls.diag

### Compute Diagnostics for `lsfit` Regression Results

### Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients.

### Usage

```
ls.diag(ls.out)
```

### Arguments

|                     |                                                 |
|---------------------|-------------------------------------------------|
| <code>ls.out</code> | Typically the result of <a href="#">lsfit()</a> |
|---------------------|-------------------------------------------------|

### Value

A list with the following numeric components.

|              |                                                                 |
|--------------|-----------------------------------------------------------------|
| std.dev      | The standard deviation of the errors, an estimate of $\sigma$ . |
| hat          | diagonal entries $h_{ii}$ of the hat matrix $H$                 |
| std.res      | standardized residuals                                          |
| stud.res     | studentized residuals                                           |
| cooks        | Cook's distances                                                |
| dfits        | DFITS statistics                                                |
| correlation  | correlation matrix                                              |
| std.err      | standard errors of the regression coefficients                  |
| cov.scaled   | Scaled covariance matrix of the coefficients                    |
| cov.unscaled | Unscaled covariance matrix of the coefficients                  |

### References

### See Also

[hat](#) for the hat matrix diagonals, [ls.print](#), [lm.influence](#), [summary.lm](#), [anova](#).

### Examples

```
##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
dlsD9 <- ls.diag(lsD9)
utils::str(dlsD9, give.attr = FALSE)
abs(1 - sum(dlsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(dlsD9$hat, dlsD9$stud.res, xlim = c(0, 0.11))
abline(h = 0, lty = 2, col = "lightgray")
```

**ls.print**

*Print lsfit Regression Results*

### Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients and prints them if `print.it` is TRUE.

### Usage

```
ls.print(ls.out, digits = 4, print.it = TRUE)
```

### Arguments

|          |                                                                |
|----------|----------------------------------------------------------------|
| ls.out   | Typically the result of <a href="#">lsfit()</a>                |
| digits   | The number of significant digits used for printing             |
| print.it | a logical indicating whether the result should also be printed |

**Value**

A list with the components

|            |                                                                       |
|------------|-----------------------------------------------------------------------|
| summary    | The ANOVA table of the regression                                     |
| coef.table | matrix with regression coefficients, standard errors, t- and p-values |

**Note**

Usually you would use `summary(lm(...))` and `anova(lm(...))` to obtain similar output.

**See Also**

`ls.diag`, `lsfit`, also for examples; `lm`, `lm.influence` which usually are preferable.

|                    |                                   |
|--------------------|-----------------------------------|
| <code>lsfit</code> | <i>Find the Least Squares Fit</i> |
|--------------------|-----------------------------------|

**Description**

The least squares estimate of  $\beta$  in the model

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

is found.

**Usage**

```
lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07,
 yname = NULL)
```

**Arguments**

|           |                                                                                    |
|-----------|------------------------------------------------------------------------------------|
| x         | a matrix whose rows correspond to cases and whose columns correspond to variables. |
| y         | the responses, possibly a matrix if you want to fit multiple left hand sides.      |
| wt        | an optional vector of weights for performing weighted least squares.               |
| intercept | whether or not an intercept term should be used.                                   |
| tolerance | the tolerance to be used in the matrix decomposition.                              |
| yname     | names to be used for the response variables.                                       |

**Details**

If weights are specified then a weighted least squares is performed with the weight given to the  $j$ th case specified by the  $j$ th entry in `wt`.

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.

**Value**

A list with the following named components:

|           |                                                                                          |
|-----------|------------------------------------------------------------------------------------------|
| coef      | the least squares estimates of the coefficients in the model ( $\beta$ as stated above). |
| residuals | residuals from the fit.                                                                  |
| intercept | indicates whether an intercept was fitted.                                               |
| qr        | the QR decomposition of the design matrix.                                               |

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**

[lm](#) which usually is preferable; [ls.print](#), [ls.diag](#).

**Examples**

```
##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = unclass(gl(2, 10)), y = weight)
ls.print(lsD9)
```

mad

*Median Absolute Deviation***Description**

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

**Usage**

```
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE,
 low = FALSE, high = FALSE)
```

**Arguments**

|          |                                                                                                                               |
|----------|-------------------------------------------------------------------------------------------------------------------------------|
| x        | a numeric vector.                                                                                                             |
| center   | Optionally, the centre: defaults to the median.                                                                               |
| constant | scale factor.                                                                                                                 |
| na.rm    | if TRUE then NA values are stripped from x before computation takes place.                                                    |
| low      | if TRUE, compute the ‘lo-median’, i.e., for even sample size, do not average the two middle values, but take the smaller one. |
| high     | if TRUE, compute the ‘hi-median’, i.e., take the larger of the two middle values for even sample size.                        |

## Details

The actual value calculated is  $\text{constant} * \text{cMedian}(\text{abs}(x - \text{center}))$  with the default value of center being `median(x)`, and `cMedian` being the usual, the ‘low’ or ‘high’ median, see the arguments description for low and high above.

The default constant = 1.4826 (approximately  $1/\Phi^{-1}(3/4) = 1/qnorm(3/4)$ ) ensures consistency, i.e.,

$$E[\text{mad}(X_1, \dots, X_n)] = \sigma$$

for  $X_i$  distributed as  $N(\mu, \sigma^2)$  and large  $n$ .

If `na.rm` is TRUE then NA values are stripped from `x` before computation takes place. If this is not done then an NA value in `x` will cause `mad` to return NA.

## See Also

[IQR](#) which is simpler but less robust, [median](#), [var](#).

## Examples

```
mad(c(1:9))
print(mad(c(1:9), constant = 1)) ==
 mad(c(1:8, 100), constant = 1) # = 2 ; TRUE
x <- c(1,2,3,5,7,8)
sort(abs(x - median(x)))
c(mad(x, constant = 1),
 mad(x, constant = 1, low = TRUE),
 mad(x, constant = 1, high = TRUE))
```

## Description

Returns the squared Mahalanobis distance of all rows in `x` and the vector  $\mu = \text{center}$  with respect to  $\Sigma = \text{cov}$ . This is (for vector `x`) defined as

$$D^2 = (x - \mu)' \Sigma^{-1} (x - \mu)$$

## Usage

```
mahalanobis(x, center, cov, inverted = FALSE, ...)
```

## Arguments

|                       |                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | vector or matrix of data with, say, $p$ columns.                                                                        |
| <code>center</code>   | mean vector of the distribution or second data vector of length $p$ .                                                   |
| <code>cov</code>      | covariance matrix ( $p \times p$ ) of the distribution.                                                                 |
| <code>inverted</code> | logical. If TRUE, <code>cov</code> is supposed to contain the <i>inverse</i> of the covariance matrix.                  |
| ...                   | passed to <a href="#">solve</a> for computing the inverse of the covariance matrix (if <code>inverted</code> is false). |

**See Also**[cov](#), [var](#)**Examples**

```
require(graphics)

ma <- cbind(1:6, 1:3)
(S <- var(ma))
mahalanobis(c(0, 0), 1:2, S)

x <- matrix(rnorm(100*3), ncol = 3)
stopifnot(mahalanobis(x, 0, diag(ncol(x))) == rowSums(x*x))
##- Here, D^2 = usual squared Euclidean distances

Sx <- cov(x)
D2 <- mahalanobis(x, colMeans(x), Sx)
plot(density(D2, bw = 0.5),
 main="Squared Mahalanobis distances, n=100, p=3") ; rug(D2)
qqplot(qchisq(ppoints(100), df = 3), D2,
 main = expression("Q-Q plot of Mahalanobis" * ~D^2 *
 " vs. quantiles of" * ~chi[3]^2))
abline(0, 1, col = gray)
```

**make.link***Create a Link for GLM Families***Description**

This function is used with the [family](#) functions in [glm\(\)](#). Given the name of a link, it returns a link function, an inverse link function, the derivative  $d\mu/d\eta$  and a function for domain checking.

**Usage**

```
make.link(link)
```

**Arguments**

|             |                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------|
| <b>link</b> | character; one of "logit", "probit", "cauchit", "cloglog", "identity", "log", "sqrt", "1/mu^2", "inverse". |
|-------------|------------------------------------------------------------------------------------------------------------|

**Value**

A object of class "link-glm", a list with components

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <b>linkfun</b>  | Link function <code>function(mu)</code>                                 |
| <b>linkinv</b>  | Inverse link function <code>function(eta)</code>                        |
| <b>mu.eta</b>   | Derivative function( <code>eta</code> ) $d\mu/d\eta$                    |
| <b>valideta</b> | <code>function(eta){ TRUE if eta is in the domain of linkinv }</code> . |
| <b>name</b>     | a name to be used for the link                                          |

**See Also**

[power](#), [glm](#), [family](#).

**Examples**

```
utils::str(make.link("logit"))
```

**makepredictcall**

*Utility Function for Safe Prediction*

**Description**

A utility to help [model.frame.default](#) create the right matrices when predicting from models with terms like poly or ns.

**Usage**

```
makepredictcall(var, call)
```

**Arguments**

|                   |                                     |
|-------------------|-------------------------------------|
| <code>var</code>  | A variable.                         |
| <code>call</code> | The term in the formula, as a call. |

**Details**

This is a generic function with methods for poly, bs and ns: the default method handles scale. If [model.frame.default](#) encounters such a term when creating a model frame, it modifies the predvars attribute of the terms supplied by replacing the term with one which will work for predicting new data. For example [makepredictcall.ns](#) adds arguments for the knots and intercept.

To make use of this, have your model-fitting function return the terms attribute of the model frame, or copy the predvars attribute of the terms attribute of the model frame to your terms object.

To extend this, make sure the term creates variables with a class, and write a suitable method for that class.

**Value**

A replacement for call for the predvars attribute of the terms.

**See Also**

[model.frame](#), [poly](#), [scale](#); [bs](#) and [ns](#) in package [splines](#).

[cars](#) for an example of prediction from a polynomial fit.

## Examples

```
require(graphics)

using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, len = 200)
lines(ht, predict(fm, data.frame(height = ht)))

see also example(cars)

see bs and ns for spline examples.
```

---

manova

*Multivariate Analysis of Variance*

---

## Description

A class for the multivariate analysis of variance.

## Usage

```
manova(...)
```

## Arguments

... Arguments to be passed to [aov](#).

## Details

Class "manova" differs from class "aov" in selecting a different `summary` method. Function `manova` calls `aov` and then add class "manova" to the result object for each stratum.

## Value

See `aov` and the comments in 'Details' here.

## References

- Krzanowski, W. J. (1988) *Principles of Multivariate Analysis. A User's Perspective*. Oxford.  
Hand, D. J. and Taylor, C. C. (1987) *Multivariate Analysis of Variance and Repeated Measures*. Chapman and Hall.

## See Also

[aov](#), [summary.manova](#), the latter containing examples.

## Examples

```
Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))

Fake a 2nd response variable
npk2 <- within(npk, foo <- rnorm(24))
(npk2.aov <- manova(cbind(yield, foo) ~ block + N*P*K, npk2))
summary(npk2.aov)

(npk2.aovE <- manova(cbind(yield, foo) ~ N*P*K + Error(block), npk2))
summary(npk2.aovE)
```

**mantelhaen.test**

*Cochran-Mantel-Haenszel Chi-Squared Test for Count Data*

## Description

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

## Usage

```
mantelhaen.test(x, y = NULL, z = NULL,
 alternative = c("two.sided", "less", "greater"),
 correct = TRUE, exact = FALSE, conf.level = 0.95)
```

## Arguments

- |             |                                                                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels. |
| y           | a factor object with at least 2 levels; ignored if x is an array.                                                                                                                      |
| z           | a factor object with at least 2 levels identifying to which stratum the corresponding elements in x and y belong; ignored if x is an array.                                            |
| alternative | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by K case.                  |
| correct     | a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by K case.                                                      |
| exact       | a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by K case.                  |
| conf.level  | confidence level for the returned confidence interval. Only used in the 2 by 2 by K case.                                                                                              |

## Details

If x is an array, each dimension must be at least 2, and the entries should be nonnegative integers. NA's are not allowed. Otherwise, x, y and z must have the same length. Triples containing NA's are removed. All variables must take at least two different values.

### Value

A list with class "htest" containing the following components:

|                          |                                                                                                                                                                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | Only present if no exact test is performed. In the classical case of a 2 by $K$ table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic. |
| <code>parameter</code>   | the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.                                                                             |
| <code>p.value</code>     | the p-value of the test.                                                                                                                                                                                                                    |
| <code>conf.int</code>    | a confidence interval for the common odds ratio. Only present in the 2 by 2 by $K$ case.                                                                                                                                                    |
| <code>estimate</code>    | an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the 2 by 2 by $K$ case.                                 |
| <code>null.value</code>  | the common odds ratio under the null of independence, 1. Only present in the 2 by 2 by $K$ case.                                                                                                                                            |
| <code>alternative</code> | a character string describing the alternative hypothesis. Only present in the 2 by 2 by $K$ case.                                                                                                                                           |
| <code>method</code>      | a character string indicating the method employed, and whether or not continuity correction was used.                                                                                                                                       |
| <code>data.name</code>   | a character string giving the names of the data.                                                                                                                                                                                            |

### Note

The asymptotic distribution is only valid if there is no three-way interaction. In the classical 2 by 2 by  $K$  case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

### Examples

```
Agresti (1990), pages 231--237, Penicillin and Rabbits
Investigation of the effectiveness of immediately injected or 1.5
hours delayed penicillin in protecting rabbits against a lethal
injection with beta-hemolytic streptococci.
Rabbits <-
array(c(0, 0, 6, 5,
 3, 0, 3, 6,
 6, 2, 0, 4,
 5, 6, 1, 0,
 2, 5, 0, 0),
 dim = c(2, 2, 5),
 dimnames = list(
 Delay = c("None", "1.5h"),
 Response = c("Cured", "Died"),
 Penicillin.Level = c("1/8", "1/4", "1/2", "1", "4")))
```

```

Rabbits
Classical Mantel-Haenszel test
mantelhaen.test(Rabbits)
=> p = 0.047, some evidence for higher cure rate of immediate
injection
Exact conditional test
mantelhaen.test(Rabbits, exact = TRUE)
=> p = 0.040
Exact conditional test for one-sided alternative of a higher
cure rate for immediate injection
mantelhaen.test(Rabbits, exact = TRUE, alternative = "greater")
=> p = 0.020

UC Berkeley Student Admissions
mantelhaen.test(UCBAdmissions)
No evidence for association between admission and gender
when adjusted for department. However,
apply(UCBAdmissions, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))
This suggests that the assumption of homogeneous (conditional)
odds ratios may be violated. The traditional approach would be
using the Woolf test for interaction:
woolf <- function(x) {
 x <- x + 1 / 2
 k <- dim(x)[3]
 or <- apply(x, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))
 w <- apply(x, 3, function(x) 1 / sum(1 / x))
 1 - pchisq(sum(w * (log(or) - weighted.mean(log(or), w)) ^ 2), k - 1)
}
woolf(UCBAdmissions)
=> p = 0.003, indicating that there is significant heterogeneity.
(And hence the Mantel-Haenszel test cannot be used.)

Agresti (2002), p. 287f and p. 297.
Job Satisfaction example.
Satisfaction <-
 as.table(array(c(1, 2, 0, 0, 3, 3, 1, 2,
 11, 17, 8, 4, 2, 3, 5, 2,
 1, 0, 0, 0, 1, 3, 0, 1,
 2, 5, 7, 9, 1, 1, 3, 6),
 dim = c(4, 4, 2),
 dimnames =
 list(Income =
 c("<5000", "5000-15000",
 "15000-25000", ">25000"),
 "Job Satisfaction" =
 c("V_D", "L_S", "M_S", "V_S"),
 Gender = c("Female", "Male"))))
(Satisfaction categories abbreviated for convenience.)
ftable(. ~ Gender + Income, Satisfaction)
Table 7.8 in Agresti (2002), p. 288.
mantelhaen.test(Satisfaction)
See Table 7.12 in Agresti (2002), p. 297.

```

## Description

Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

## Usage

```
mauchly.test(object, ...)
S3 method for class m1m
mauchly.test(object, ...)
S3 method for class SSD
mauchly.test(object, Sigma = diag(nrow = p),
 T = Thin.row(proj(M) - proj(X)), M = diag(nrow = p), X = ~0,
 idata = data.frame(index = seq_len(p)), ...)
```

## Arguments

|               |                                                                         |
|---------------|-------------------------------------------------------------------------|
| <b>object</b> | object of class <b>SSD</b> or <b>m1m</b> .                              |
| <b>Sigma</b>  | matrix to be proportional to.                                           |
| <b>T</b>      | transformation matrix. By default computed from <b>M</b> and <b>X</b> . |
| <b>M</b>      | formula or matrix describing the outer projection (see below).          |
| <b>X</b>      | formula or matrix describing the inner projection (see below).          |
| <b>idata</b>  | data frame describing intra-block design.                               |
| <b>...</b>    | arguments to be passed to or from other methods.                        |

## Details

Mauchly's test test for whether a covariance matrix can be assumed to be proportional to a given matrix.

This is a generic function with methods for classes "**m1m**" and "**SSD**".

The basic method is for objects of class **SSD** the method for **m1m** objects just extracts the **SSD** matrix and invokes the corresponding method with the same options and arguments.

The **T** argument is used to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A matrix **T** can be given directly or specified as the difference between two projections onto the spaces spanned by **M** and **X**, which in turn can be given as matrices or as model formulas with respect to **idata** (the tests will be invariant to parametrization of the quotient space **M/X**).

The common use of this test is in repeated measurements designs, with **X** = ~1. This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.

Notice that the defaults involve **p**, which is calculated internally as the dimension of the **SSD** matrix, and a couple of hidden functions in the **stats** namespace, namely **proj** which calculates projection matrices from design matrices or model formulas and **Thin.row** which removes linearly dependent rows from a matrix until it has full row rank.

## Value

An object of class "**htest**"

**Note**

The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in R.

**References**

T. W. Anderson (1958). *An Introduction to Multivariate Statistical Analysis*. Wiley.

**See Also**

[SSD](#), [anova.mlm](#), [rWishart](#)

**Examples**

```
utils::example(SSD) # Brings in the mlmfit and reacttime objects

traditional test of intrasubj. contrasts
mauchly.test(mlmfit, X = ~1)

tests using intra-subject 3x2 design
idata <- data.frame(deg = gl(3, 1, 6, labels = c(0,4,8)),
 noise = gl(2, 3, 6, labels = c("A","P")))
mauchly.test(mlmfit, X = ~ deg + noise, idata = idata)
mauchly.test(mlmfit, M = ~ deg + noise, X = ~ noise, idata = idata)
```

**mcnemar.test**

*McNemar's Chi-squared Test for Count Data*

**Description**

Performs McNemar's chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

**Usage**

```
mcnemar.test(x, y = NULL, correct = TRUE)
```

**Arguments**

- |                      |                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------|
| <code>x</code>       | either a two-dimensional contingency table in matrix form, or a factor object.                 |
| <code>y</code>       | a factor object; ignored if <code>x</code> is a matrix.                                        |
| <code>correct</code> | a logical indicating whether to apply continuity correction when computing the test statistic. |

**Details**

The null is that the probabilities of being classified into cells  $[i, j]$  and  $[j, i]$  are the same.

If `x` is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both `x` and `y` must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.

Continuity correction is only used in the 2-by-2 case if `correct` is TRUE.

## Value

A list with class "htest" containing the following components:

|           |                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------|
| statistic | the value of McNemar's statistic.                                                                     |
| parameter | the degrees of freedom of the approximate chi-squared distribution of the test statistic.             |
| p.value   | the p-value of the test.                                                                              |
| method    | a character string indicating the type of test performed, and whether continuity correction was used. |
| data.name | a character string giving the name(s) of the data.                                                    |

## References

Alan Agresti (1990). *Categorical data analysis*. New York: Wiley. Pages 350–354.

## Examples

```
Agresti (1990), p. 350.
Presidential Approval Ratings.
Approval of the Presidents performance in office in two surveys,
one month apart, for a random sample of 1600 voting-age Americans.
Performance <-
matrix(c(794, 86, 150, 570),
 nrow = 2,
 dimnames = list("1st Survey" = c("Approve", "Disapprove"),
 "2nd Survey" = c("Approve", "Disapprove")))
Performance
mcnemar.test(Performance)
=> significant change (in fact, drop) in approval ratings
```

median

*Median Value*

## Description

Compute the sample median.

## Usage

```
median(x, na.rm = FALSE)
```

## Arguments

|       |                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------|
| x     | an object for which a method has been defined, or a numeric vector containing the values whose median is to be computed. |
| na.rm | a logical value indicating whether NA values should be stripped before the computation proceeds.                         |

## Details

This is a generic function for which methods can be written. However, the default method makes use of `is.na`, `sort` and `mean` from package **base** all of which are generic, and so the default method will work for most classes (e.g. “[Date](#)”) for which a median is a reasonable concept.

## Value

The default method returns a length-one object of the same type as `x`, except when `x` is integer of even length, when the result will be double.

If there are no values or if `na.rm = FALSE` and there are NA values the result is NA of the same type as `x` (or more generally the result of `x[FALSE][NA]`).

## See Also

[quantile](#) for general quantiles.

## Examples

```
median(1:4) # = 2.5 [even number]
median(c(1:3, 100, 1000)) # = 3 [odd, robust]
```

medpolish

*Median Polish of a Matrix*

## Description

Fits an additive model using Tukey’s *median polish* procedure.

## Usage

```
medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE,
 na.rm = FALSE)
```

## Arguments

|                         |                                                                         |
|-------------------------|-------------------------------------------------------------------------|
| <code>x</code>          | a numeric matrix.                                                       |
| <code>eps</code>        | real number greater than 0. A tolerance for convergence: see ‘Details’. |
| <code>maxiter</code>    | the maximum number of iterations                                        |
| <code>trace.iter</code> | logical. Should progress in convergence be reported?                    |
| <code>na.rm</code>      | logical. Should missing values be removed?                              |

## Details

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than `eps` or until there have been `maxiter` iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if `trace.iter` is TRUE. If `na.rm` is FALSE the presence of any NA value in `x` will cause an error, otherwise NA values are ignored.

`medpolish` returns an object of class `medpolish` (see below). There are printing and plotting methods for this class, which are invoked via by the generics `print` and `plot`.

## Value

An object of class `medpolish` with the following named components:

|                        |                            |
|------------------------|----------------------------|
| <code>overall</code>   | the fitted constant term.  |
| <code>row</code>       | the fitted row effects.    |
| <code>col</code>       | the fitted column effects. |
| <code>residuals</code> | the residuals.             |
| <code>name</code>      | the name of the dataset.   |

## References

## See Also

`median`; `aov` for a *mean* instead of *median* decomposition.

## Examples

```
require(graphics)

Deaths from sport parachuting; from ABC of EDA, p.224:
deaths <-
 rbind(c(14,15,14),
 c(7, 4, 7),
 c(8, 2,10),
 c(15, 9,10),
 c(0, 2, 0))
dimnames(deaths) <- list(c("1-24", "25-74", "75-199", "200++", "NA"),
 paste(1973:1975))
deaths
(med.d <- medpolish(deaths))
plot(med.d)
Check decomposition:
all(deaths ==
 med.d$overall + outer(med.d$row,med.d$col, "+") + med.d$residuals)
```

|                            |                                              |
|----------------------------|----------------------------------------------|
| <code>model.extract</code> | <i>Extract Components from a Model Frame</i> |
|----------------------------|----------------------------------------------|

## Description

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to `model.frame`.

## Usage

```
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```

## Arguments

|                             |                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>frame, x, data</code> | A model frame.                                                                                                  |
| <code>component</code>      | literal character string or name. The name of a component to extract, such as "weights", "subset".              |
| <code>type</code>           | One of "any", "numeric", "double". Using either of latter two coerces the result to have storage mode "double". |

## Details

`model.extract` is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the `etastart` and `mustart` components of a `glm` fit.

`model.offset` and `model.response` are equivalent to `model.extract(, "offset")` and `model.extract(, "response")` respectively. `model.offset` sums any terms specified by `offset` terms in the formula or by `offset` arguments in the call producing the model frame: it does check that the offset is numeric.

`model.weights` is slightly different from `model.frame(, "weights")` in not naming the vector it returns.

## Value

The specified component of the model frame, usually a vector.

## See Also

`model.frame`, `offset`

## Examples

```
a <- model.frame(cbind(ncases,ncontrols) ~ agegp + tobgp + alcgp, data = esoph)
model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases+ncontrols) ~ agegp + tobgp + alcgp,
 data = esoph, weights = ncases+ncontrols)
model.response(a)
```

```

model.extract(a, "weights")

a <- model.frame(cbind(ncases,ncontrols) ~ agegp,
 something = tobgp, data = esoph)
names(a)
stopifnot(model.extract(a, "something") == esoph$tobgp)

```

**model.frame***Extracting the Model Frame from a Formula or Fit***Description**

`model.frame` (a generic function) and its methods return a [data.frame](#) with the variables needed to use `formula` and any ... arguments.

**Usage**

```

model.frame(formula, ...)

Default S3 method:
model.frame(formula, data = NULL,
 subset = NULL, na.action = na.fail,
 drop.unused.levels = FALSE, xlev = NULL, ...)

S3 method for class aovlist
model.frame(formula, data = NULL, ...)

S3 method for class glm
model.frame(formula, ...)

S3 method for class lm
model.frame(formula, ...)

get_all_vars(formula, data, ...)

```

**Arguments**

|                                 |                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>            | a model <a href="#">formula</a> or <a href="#">terms</a> object or an R object.                                                                                                                                                                                                                                                  |
| <code>data</code>               | a <code>data.frame</code> , list or environment (or object coercible by <a href="#">as.data.frame</a> to a <code>data.frame</code> ), containing the variables in <code>formula</code> . Neither a matrix nor an array will be accepted.                                                                                         |
| <code>subset</code>             | a specification of the rows to be used: defaults to all rows. This can be any valid indexing vector (see <a href="#">[.data.frame]</a> ) for the rows of <code>data</code> or if that is not supplied, a data frame made up of the variables used in <code>formula</code> .                                                      |
| <code>na.action</code>          | how NAs are treated. The default is first, any <code>na.action</code> attribute of <code>data</code> , second a <code>na.action</code> setting of <a href="#">options</a> , and third <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . Another possible value is <code>NULL</code> . |
| <code>drop.unused.levels</code> | should factors have unused levels dropped? Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                      |
| <code>xlev</code>               | a named list of character vectors giving the full set of levels to be assumed for each factor.                                                                                                                                                                                                                                   |

...

further arguments such as `data`, `na.action`, `subset`. Any additional arguments such as `offset` and `weights` which reach the default method are used to create further columns in the model frame, with parenthesised names such as `"(offset)"`.

## Details

Exactly what happens depends on the class and attributes of the object `formula`. If this is an object of fitted-model class such as `"lm"`, the method will either return the saved model frame used when fitting the model (if any, often selected by argument `model = TRUE`) or pass the call used when fitting on to the default method. The default method itself can cope with rather standard model objects such as those of class `"lqs"` from package **MASS** if no other arguments are supplied.

The rest of this section applies only to the default method.

If either `formula` or `data` is already a model frame (a data frame with a `"terms"` attribute) and the other is missing, the model frame is returned. Unless `formula` is a `terms` object, as.`formula` and then `terms` is called on it. (If you wish to use the `keep.order` argument of `terms.formula`, pass a `terms` object rather than a `formula`.)

Row names for the model frame are taken from the `data` argument if present, then from the names of the response in the `formula` (or `rownames` if it is a matrix), if there is one.

All the variables in `formula`, `subset` and in `...` are looked for first in `data` and then in the environment of `formula` (see the help for `formula()` for further details) and collected into a data frame. Then the `subset` expression is evaluated, and it is used as a row index to the data frame. Then the `na.action` function is applied to the data frame (and may well add attributes). The levels of any factors in the data frame are adjusted according to the `drop.unused.levels` and `xlev` arguments: if `xlev` specifies a factor and a character variable is found, it is converted to a factor (as from R 2.10.0).

Unless `na.action = NULL`, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that *all* the variables in the `formula` are included in the data frame, even those preceded by `-`.

Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.

`get_all_vars` returns a `data.frame` containing the variables used in `formula` plus those specified `....` Unlike `model.frame.default`, it returns the input variables and not those resulting from function calls in `formula`.

## Value

A `data.frame` containing the variables used in `formula` plus those specified in `....` It will have additional attributes, including `"terms"` for an object of class `"terms"` derived from `formula`, and possibly `"na.action"` giving information on the handling of NAs (which will not be present if no special handling was done, e.g. by `na.pass`).

```

---

model.matrix

*Construct Design Matrices*

---

## Description

`model.matrix` creates a design (or model) matrix.

## Usage

```
model.matrix(object, ...)

Default S3 method:
model.matrix(object, data = environment(object),
 contrasts.arg = NULL, xlev = NULL, ...)
```

## Arguments

|                            |                                                                                                                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>        | an object of an appropriate class. For the default method, a model <a href="#">formula</a> or a <a href="#">terms</a> object.                                                                                                                                           |
| <code>data</code>          | a data frame created with <a href="#">model.frame</a> . If another sort of object, <code>model.frame</code> is called first.                                                                                                                                            |
| <code>contrasts.arg</code> | A list, whose entries are values (numeric matrices or character strings naming functions) to be used as replacement values for the <a href="#">contrasts</a> replacement function and whose names are the names of columns of data containing <a href="#">factors</a> . |
| <code>xlev</code>          | to be used as argument of <a href="#">model.frame</a> if <code>data</code> is such that <code>model.frame</code> is called.                                                                                                                                             |
| <code>...</code>           | further arguments passed to or from other methods.                                                                                                                                                                                                                      |

## Details

`model.matrix` creates a design matrix from the description given in `terms(object)`, using the data in `data` which must supply variables with the same names as would be created by a call to `model.frame(object)` or, more precisely, by evaluating `attr(terms(object), "variables")`. If `data` is a data frame, there may be other columns and the order of columns is not important. Any character variables are coerced to factors. After coercion, all the variables used on the right-hand side of the formula must be logical, integer, numeric or factor.

If `contrasts.arg` is specified for a factor it overrides the default factor coding for that variable and any “contrasts” attribute set by `C` or `contrasts`.

In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula (and not in the term), so in `~ a + b + b:a` the interaction will have a varying fastest.

By convention, if the response variable also appears on the right-hand side of the formula it is dropped (with a warning), although interactions involving the term are retained.

### Value

The design matrix for a regression-like model with the specified formula and data.

There is an attribute "assign", an integer vector with an entry for each column in the matrix giving the term in the formula which gave rise to the column. Value 0 corresponds to the intercept (if any), and positive values to terms in the order given by the `term.labels` attribute of the `terms` structure corresponding to `object`.

If there are any factors in terms in the model, there is an attribute "contrasts", a named list with an entry for each factor. This specifies the contrasts that would be used in terms in which the factor is coded by contrasts (in some terms dummy coding may be used), either as a character vector naming a function or as a numeric matrix.

### See Also

`model.frame`, `model.extract`, `terms`

### Examples

```
ff <- log(Volume) ~ log(Height) + log(Girth)
utils::str(m <- model.frame(ff, trees))
mat <- model.matrix(ff, m)

dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts")
model.matrix(~ a + b, dd)
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum"))
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum", b = "contr.poly"))
m.orth <- model.matrix(~a+b, dd, contrasts = list(a = "contr.helmert"))
crossprod(m.orth) # m.orth is ALMOST orthogonal
```

`model.tables`

*Compute Tables of Results from an Aov Model Fit*

### Description

Computes summary tables for model fits, especially complex `aov` fits.

### Usage

```
model.tables(x, ...)

S3 method for class aov
model.tables(x, type = "effects", se = FALSE, cterms, ...)

S3 method for class aovlist
model.tables(x, type = "effects", se = FALSE, ...)
```

### Arguments

|        |                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------|
| x      | a model object, usually produced by aov                                                                          |
| type   | type of table: currently only "effects" and "means" are implemented.                                             |
| se     | should standard errors be computed?                                                                              |
| cterms | A character vector giving the names of the terms for which tables should be computed. The default is all tables. |
| ...    | further arguments passed to or from other methods.                                                               |

### Details

For type = "effects" give tables of the coefficients for each term, optionally with standard errors.

For type = "means" give tables of the mean response for each combinations of levels of the factors in a term.

The "aov" method cannot be applied to components of a "aovlist" fit.

### Value

An object of class "tables.aov", as list which may contain components

|        |                                            |
|--------|--------------------------------------------|
| tables | A list of tables for each requested term.  |
| n      | The replication information for each term. |
| se     | Standard error information.                |

### Warning

The implementation is incomplete, and only the simpler cases have been tested thoroughly.

Weighted aov fits are not supported.

### See Also

[aov](#), [proj](#), [replications](#), [TukeyHSD](#), [se.contrast](#)

### Examples

```
options(contrasts = c("contr.helmert", "contr.treatment"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
model.tables(npk.aov, "means", se = TRUE)

as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
model.tables(npk.aovE, se = TRUE)
model.tables(npk.aovE, "means")
```

---

**monthplot***Plot a Seasonal or other Subseries from a Time Series*

---

## Description

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

## Usage

```
monthplot(x, ...)

S3 method for class stl
monthplot(x, labels = NULL, ylab = choice, choice = "seasonal",
 ...)

S3 method for class StructTS
monthplot(x, labels = NULL, ylab = choice, choice = "sea", ...)

S3 method for class ts
monthplot(x, labels = NULL, times = time(x), phase = cycle(x),
 ylab = deparse(substitute(x)), ...)

Default S3 method:
monthplot(x, labels = 1L:12L,
 ylab = deparse(substitute(x)),
 times = seq_along(x),
 phase = (times - 1L)%%length(labels) + 1L, base = mean,
 axes = TRUE, type = c("l", "h"), box = TRUE,
 add = FALSE,
 col = par("col"), lty = par("lty"), lwd = par("lwd"),
 col.base = col, lty.base = lty, lwd.base = lwd, ...)
```

## Arguments

|               |                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------|
| <b>x</b>      | Time series or related object.                                                                            |
| <b>labels</b> | Labels to use for each ‘season’.                                                                          |
| <b>ylab</b>   | y label.                                                                                                  |
| <b>times</b>  | Time of each observation.                                                                                 |
| <b>phase</b>  | Indicator for each ‘season’.                                                                              |
| <b>base</b>   | Function to use for reference line for subseries.                                                         |
| <b>choice</b> | Which series of an <b>stl</b> or <b>StructTS</b> object?                                                  |
| <b>...</b>    | Arguments to be passed to the default method or graphical parameters.                                     |
| <b>axes</b>   | Should axes be drawn (ignored if <b>add</b> = <b>TRUE</b> )?                                              |
| <b>type</b>   | Type of plot. The default is to join the points with lines, and “h” is for histogram-like vertical lines. |
| <b>box</b>    | Should a box be drawn (ignored if <b>add</b> = <b>TRUE</b> )?                                             |
| <b>add</b>    | Should thus just add on an existing plot.                                                                 |

```
col, lty, lwd Graphics parameters for the series.
col.base, lty.base, lwd.base
 Graphics parameters for the segments used for the reference lines.
```

## Details

These functions extract subseries from a time series and plot them all in one frame. The [ts](#), [stl](#), and [StructTS](#) methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the `labels` are not given but the `phase` is given, then the `labels` default to the unique values of the `phase`. If both are given, then the `phase` values are assumed to be indices into the `labels` array, i.e., they should be in the range from 1 to `length(labels)`.

## Value

These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.

**mood.test***Mood Two-Sample Test of Scale*

---

## Description

Performs Mood's two-sample test for a difference in scale parameters.

## Usage

```

mood.test(x, ...)

Default S3 method:
mood.test(x, y,
 alternative = c("two.sided", "less", "greater"), ...)

S3 method for class formula
mood.test(formula, data, subset, na.action, ...)

```

## Arguments

|                          |                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>        | numeric vectors of data values.                                                                                                                                                                                         |
| <code>alternative</code> | indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.                                                                                     |
| <code>formula</code>     | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.                         |
| <code>data</code>        | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>      | an optional vector specifying a subset of observations to be used.                                                                                                                                                      |
| <code>na.action</code>   | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                              |
| <code>...</code>         | further arguments to be passed to or from methods.                                                                                                                                                                      |

## Details

The underlying model is that the two samples are drawn from  $f(x - l)$  and  $f((x - l)/s)$ , respectively, where  $l$  is a common location parameter and  $s$  is a scale parameter.

The null hypothesis is  $s = 1$ .

There are more useful tests for this problem.

In the case of ties, the formulation of Mielke (1967) is employed.

## Value

A list with class "htest" containing the following components:

|                          |                                                           |
|--------------------------|-----------------------------------------------------------|
| <code>statistic</code>   | the value of the test statistic.                          |
| <code>p.value</code>     | the p-value of the test.                                  |
| <code>alternative</code> | a character string describing the alternative hypothesis. |
| <code>method</code>      | the character string "Mood two-sample test of scale".     |
| <code>data.name</code>   | a character string giving the names of the data.          |

## Examples

```
Same data as for the Ansari-Bradley test:
Serum iron determination using Hyland control sera
ramsay <- c(111, 107, 100, 99, 102, 106, 109, 108, 104, 99,
 101, 96, 97, 102, 107, 113, 116, 113, 110, 98)
jung.parekh <- c(107, 108, 106, 98, 105, 103, 110, 105, 104,
 100, 96, 108, 103, 104, 114, 114, 113, 108, 106, 99)
mood.test(ramsay, jung.parekh)
Compare this to ansari.test(ramsay, jung.parekh)
```

## Description

Generate multinomially distributed random number vectors and compute multinomial probabilities.

## Usage

```
rmultinom(n, size, prob)
dmultinom(x, size = NULL, prob, log = FALSE)
```

## Arguments

- |                   |                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | vector of length $K$ of integers in 0:size.                                                                                                                                                    |
| <code>n</code>    | number of random vectors to draw.                                                                                                                                                              |
| <code>size</code> | integer, say $N$ , specifying the total number of objects that are put into $K$ boxes in the typical multinomial experiment. For <code>dmultinom</code> , it defaults to <code>sum(x)</code> . |
| <code>prob</code> | numeric non-negative vector of length $K$ , specifying the probability for the $K$ classes; is internally normalized to sum 1.                                                                 |
| <code>log</code>  | logical; if TRUE, log probabilities are computed.                                                                                                                                              |

## Details

If  $x$  is a  $K$ -component vector, `dmultinom(x, prob)` is the probability

$$P(X_1 = x_1, \dots, X_K = x_k) = C \times \prod_{j=1}^K \pi_j^{x_j}$$

where  $C$  is the ‘multinomial coefficient’  $C = N!/(x_1! \cdots x_K!)$  and  $N = \sum_{j=1}^K x_j$ . By definition, each component  $X_j$  is binomially distributed as `Bin(size, prob[j])` for  $j = 1, \dots, K$ .

The `rmultinom()` algorithm draws binomials  $X_j$  from  $Bin(n_j, P_j)$  sequentially, where  $n_1 = N$  ( $N := size$ ),  $P_1 = \pi_1$  ( $\pi$  is `prob` scaled to sum 1), and for  $j \geq 2$ , recursively,  $n_j = N - \sum_{k=1}^{j-1} X_k$  and  $P_j = \pi_j / (1 - \sum_{k=1}^{j-1} \pi_k)$ .

## Value

For `rmultinom()`, an integer  $K \times n$  matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to `size`. Whereas the *transposed* result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

## Note

`dmultinom` is currently *not vectorized* at all and has no C interface (API); this may be amended in the future.

## See Also

[Distributions](#) for standard distributions, including `dbinom` which is a special case conceptually.

## Examples

```
rmultinom(10, size = 12, prob = c(0.1,0.2,0.8))

pr <- c(1,3,6,10) # normalization not necessary for generation
rmultinom(10, 20, prob = pr)

all possible outcomes of Multinom(N = 3, K = 3)
X <- t(as.matrix(expand.grid(0:3, 0:3))); X <- X[, colSums(X) <= 3]
X <- rbind(X, 3:3 - colSums(X)); dimnames(X) <- list(letters[1:3], NULL)
X
round(apply(X, 2, function(x) dmultinom(x, prob = c(1,2,5))), 3)
```

## Description

Extract information on the NA action used to create an object.

## Usage

```
na.action(object, ...)
```

**Arguments**

- object            any object whose `NA` action is given.  
...                further arguments special methods could require.

**Details**

`na.action` is a generic function, and `na.action.default` its default method. The latter extracts the "na.action" component of a list if present, otherwise the "na.action" attribute.

When `model.frame` is called, it records any information on NA handling in a "na.action" attribute. Most model-fitting functions return this as a component of their result.

**Value**

Information from the action which was applied to `object` if NAs were handled specially, or `NULL`.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

`options("na.action")`, `na.omit`, `na.fail`, also for `na.exclude`, `na.pass`.

**Examples**

```
na.action(na.omit(c(1, NA)))
```

---

na.contiguous          *Find Longest Contiguous Stretch of non-NAs*

---

**Description**

Find the longest consecutive stretch of non-missing values in a time series object. (In the event of a tie, the first such stretch.)

**Usage**

```
na.contiguous(object, ...)
```

**Arguments**

- object            a univariate or multivariate time series.  
...                further arguments passed to or from other methods.

**Value**

A time series without missing values. The class of `object` will be preserved.

**See Also**

`na.omit` and `na.omit.ts`; `na.fail`

## Examples

```
na.contiguous(presidents)
```

**na.fail**

*Handle Missing Values in Objects*

## Description

These generic functions are useful for dealing with [NAs](#) in e.g., data frames. `na.fail` returns the object if it does not contain any missing values, and signals an error otherwise. `na.omit` returns the object with incomplete cases removed. `na.pass` returns the object unchanged.

## Usage

```
na.fail(object, ...)
na.omit(object, ...)
na.exclude(object, ...)
na.pass(object, ...)
```

## Arguments

- |                     |                                                  |
|---------------------|--------------------------------------------------|
| <code>object</code> | an R object, typically a data frame              |
| ...                 | further arguments special methods could require. |

## Details

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If `na.omit` removes cases, the row numbers of the cases form the "na.action" attribute of the result, of class "omit".

`na.exclude` differs from `na.omit` only in the class of the "na.action" attribute of the result, which is "exclude". This gives different behaviour in functions making use of `naresid` and `napredict`: when `na.exclude` is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by `na.exclude`.

## References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

## See Also

`na.action`; `options` with argument `na.action` for setting NA actions; and `lm` and `glm` for functions using these. `na.contiguous` as alternative for time series.

## Examples

```
DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))
na.omit(DF)
m <- as.matrix(DF)
na.omit(m)
stopifnot(all(na.omit(1:3) == 1:3)) # does not affect objects with no NAs
try(na.fail(DF)) #> Error: missing values in ...
options("na.action")
```

---

naprint

*Adjust for Missing Values*

---

## Description

Use missing value information to report the effects of an `na.action`.

## Usage

```
naprint(x, ...)
```

## Arguments

- |     |                                                           |
|-----|-----------------------------------------------------------|
| x   | An object produced by an <code>na.action</code> function. |
| ... | further arguments passed to or from other methods.        |

## Details

This is a generic function, and the exact information differs by method. `naprint.omit` reports the number of rows omitted: `naprint.default` reports an empty string.

## Value

A character string providing information on missing values, for example the number.

---

naresid

*Adjust for Missing Values*

---

## Description

Use missing value information to adjust residuals and predictions.

## Usage

```
naresid(omit, x, ...)
napredict(omit, x, ...)
```

### Arguments

|                   |                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>omit</code> | an object produced by an <code>na.action</code> function, typically the "na.action" attribute of the result of <code>na.omit</code> or <code>na.exclude</code> . |
| <code>x</code>    | a vector, data frame, or matrix to be adjusted based upon the missing value information.                                                                         |
| <code>...</code>  | further arguments passed to or from other methods.                                                                                                               |

### Details

These are utility functions used to allow `predict`, `fitted` and `residuals` methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, "`lm`", "`glm`" and "`nls`" methods, and by further methods in packages **MASS**, **rpart** and **survival**. Also used for the scores returned by `factanal`, `prcomp` and `princomp`.

The default methods do nothing. The default method for the `na.exclude` action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently `naresid` and `napredict` are identical, but future methods need not be. `naresid` is used for residuals, and `napredict` for fitted values, predictions and `weights`.

### Value

These return a similar object to `x`.

### Note

In the early 2000s, packages **rpart** and **survival5** contained versions of these functions that had an `na.omit` action equivalent to that now used for `na.exclude`.

### Description

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters `size` and `prob`.

### Usage

```
dnbinom(x, size, prob, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbnom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
```

### Arguments

|                |                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------|
| <code>x</code> | vector of (non-negative integer) quantiles.                                                               |
| <code>q</code> | vector of quantiles.                                                                                      |
| <code>p</code> | vector of probabilities.                                                                                  |
| <code>n</code> | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |

|                         |                                                                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>size</code>       | target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive, need not be integer. |
| <code>prob</code>       | probability of success in each trial. $0 < \text{prob} \leq 1$ .                                                                                                        |
| <code>mu</code>         | alternative parametrization via mean: see ‘Details’.                                                                                                                    |
| <code>log, log.p</code> | logical; if TRUE, probabilities p are given as log(p).                                                                                                                  |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                                                                                   |

### Details

The negative binomial distribution with `size = n` and `prob = p` has density

$$p(x) = \frac{\Gamma(x+n)}{\Gamma(n)x!} p^n (1-p)^x$$

for  $x = 0, 1, 2, \dots, n > 0$  and  $0 < p \leq 1$ .

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached. The mean is  $n(1-p)/p$  and variance  $n(1-p)/p^2$ .

A negative binomial distribution can also arise as a mixture of Poisson distributions with mean distributed as a gamma distribution (see [pgamma](#)) with scale parameter  $(1 - \text{prob})/\text{prob}$  and shape parameter `size`. (This definition allows non-integer values of `size`.)

An alternative parametrization (often used in ecology) is by the *mean* `mu`, and `size`, the *dispersion parameter*, where `prob = size/(size+mu)`. The variance is `mu + mu^2/size` in this parametrization.

If an element of `x` is not integer, the result of `dnbino`m is zero, with a warning.

The case `size == 0` is the distribution concentrated at zero. This is the limiting distribution for `size` approaching zero, even if `mu` rather than `prob` is held constant. Notice though, that the mean of the limit distribution is 0, whatever the value of `mu`.

The quantile is defined as the smallest value `x` such that  $F(x) \geq p$ , where `F` is the distribution function.

### Value

`dnbino`m gives the density, `pnbino`m gives the distribution function, `qnbinom` gives the quantile function, and `rnbino`m generates random deviates.

Invalid `size` or `prob` will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rnbino`m, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

### Source

`dnbino`m computes via binomial probabilities, using code contributed by Catherine Loader (see [dbinom](#)).

`pnbino`m uses [pbeta](#).

`qnbinom` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

`rnbino`m uses the derivation as a gamma mixture of Poissons, see

Devroye, L. (1986) *Non-Uniform Random Variate Generation*. Springer-Verlag, New York. Page 480.

**See Also**

[Distributions](#) for standard distributions, including `dbinom` for the binomial, `dpois` for the Poisson and `dgeom` for the geometric distribution, which is a special case of the negative binomial.

**Examples**

```
require(graphics)
x <- 0:11
dnbinom(x, size = 1, prob = 1/2) * 2^(1 + x) # == 1
126 / dnbinom(0:8, size = 2, prob = 1/2) #- theoretically integer

Cumulative (p) = Sum of discrete prob.s (d); Relative error :
summary(1 - cumsum(dnbinom(x, size = 2, prob = 1/2)) /
pnbinom(x, size = 2, prob = 1/2))

x <- 0:15
size <- (1:20)/4
persp(x, size, dnb <- outer(x, size, function(x,s) dnbinom(x, s, prob = 0.4)),
 xlab = "x", ylab = "s", zlab = "density", theta = 150)

Alternative parametrization
x1 <- rnbinom(500, mu = 4, size = 1)
x2 <- rnbinom(500, mu = 4, size = 10)
x3 <- rnbinom(500, mu = 4, size = 100)
h1 <- hist(x1, breaks = 20, plot = FALSE)
h2 <- hist(x2, breaks = h1$breaks, plot = FALSE)
h3 <- hist(x3, breaks = h1$breaks, plot = FALSE)
barplot(rbind(h1$counts, h2$counts, h3$counts),
 beside = TRUE, col = c("red","blue","cyan"),
 names.arg = round(h1$breaks[-length(h1$breaks)]))
```

**Description**

`nextn` returns the smallest integer, greater than or equal to `n`, which can be obtained as a product of powers of the values contained in `factors`. `nextn` is intended to be used to find a suitable length to zero-pad the argument of `fft` so that the transform is computed quickly. The default value for `factors` ensures this.

**Usage**

```
nextn(n, factors = c(2,3,5))
```

**Arguments**

|                      |                                       |
|----------------------|---------------------------------------|
| <code>n</code>       | an integer.                           |
| <code>factors</code> | a vector of positive integer factors. |

**See Also**

[convolve](#), [fft](#).

**Examples**

```
nextn(1001) # 1024
table(sapply(599:630, nextn))
```

---

**nlm***Non-Linear Minimization*

---

**Description**

This function carries out a minimization of the function *f* using a Newton-type algorithm. See the references for details.

**Usage**

```
nlm(f, p, ..., hessian = FALSE, typsize = rep(1, length(p)),
 fscale = 1, print.level = 0, ndigit = 12, gradtol = 1e-6,
 stepmax = max(1000 * sqrt(sum((p/typsize)^2)), 1000),
 steptol = 1e-6, iterlim = 100, check.analyticals = TRUE)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>f</i>           | the function to be minimized, returning a single numeric value. This should be a function with first argument a vector of the length of <i>p</i> followed by any other arguments specified by the ... argument.<br>If the function value has an attribute called <i>gradient</i> or both <i>gradient</i> and <i>hessian</i> attributes, these will be used in the calculation of updated parameter values. Otherwise, numerical derivatives are used. <a href="#">deriv</a> returns a function with suitable <i>gradient</i> attribute and optionally a <i>hessian</i> attribute. |
| <i>p</i>           | starting parameter values for the minimization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ...                | additional arguments to be passed to <i>f</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>hessian</i>     | if TRUE, the <i>hessian</i> of <i>f</i> at the minimum is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>typsize</i>     | an estimate of the size of each parameter at the minimum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>fscale</i>      | an estimate of the size of <i>f</i> at the minimum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>print.level</i> | this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.                                                                                                                                                                                                                                                                                                |
| <i>ndigit</i>      | the number of significant digits in the function <i>f</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>gradtol</i>     | a positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm. The scaled gradient is a measure of the relative change in <i>f</i> in each direction <i>p[i]</i> divided by the relative change in <i>p[i]</i> .                                                                                                                                                                                                                                                                                              |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stepmax           | a positive scalar which gives the maximum allowable scaled step length. stepmax is used to prevent steps which would cause the optimization function to overflow, to prevent the algorithm from leaving the area of interest in parameter space, or to detect divergence in the algorithm. stepmax would be chosen small enough to prevent the first two of these occurrences, but should be larger than any anticipated reasonable step. |
| steptol           | A positive scalar providing the minimum allowable relative step length.                                                                                                                                                                                                                                                                                                                                                                   |
| iterlim           | a positive integer specifying the maximum number of iterations to be performed before the program is terminated.                                                                                                                                                                                                                                                                                                                          |
| check.analyticals | a logical scalar specifying whether the analytic gradients and Hessians, if they are supplied, should be checked against numerical derivatives at the initial parameter values. This can help detect incorrectly formulated gradients or Hessians.                                                                                                                                                                                        |

## Details

Note that arguments after . . . must be matched exactly.

If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if check.analyticals = TRUE (the default) with a warning. The hessian is not even checked unless the gradient is present and passes the sanity checks.

From the three methods available in the original source, we always use method “1” which is line search.

The functions supplied should always return finite (including not NA and not NaN) values: for the function value itself non-finite values are replaced by the maximum positive value with a warning.

The parameter vector passed to f and hessian has special semantics and is shared between calls. The functions should not copy it.

## Value

A list containing the following components:

|            |                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| minimum    | the value of the estimated minimum of f.                                                                                                                                                                |
| estimate   | the point at which the minimum value of f is obtained.                                                                                                                                                  |
| gradient   | the gradient at the estimated minimum of f.                                                                                                                                                             |
| hessian    | the hessian at the estimated minimum of f (if requested).                                                                                                                                               |
| code       | an integer indicating why the optimization process terminated.                                                                                                                                          |
|            | <b>1:</b> relative gradient is close to zero, current iterate is probably solution.                                                                                                                     |
|            | <b>2:</b> successive iterates within tolerance, current iterate is probably solution.                                                                                                                   |
|            | <b>3:</b> last global step failed to locate a point lower than estimate. Either estimate is an approximate local minimum of the function or steptol is too small.                                       |
|            | <b>4:</b> iteration limit exceeded.                                                                                                                                                                     |
|            | <b>5:</b> maximum step size stepmax exceeded five consecutive times. Either the function is unbounded below, becomes asymptotic to a finite value from above in some direction or stepmax is too small. |
| iterations | the number of iterations performed.                                                                                                                                                                     |

## Examples

```
f <- function(x) sum((x-1:length(x))^2)
nlm(f, c(10,10))
nlm(f, c(10,10), print.level = 2)
utils::str(nlm(f, c(5), hessian = TRUE))

f <- function(x, a) sum((x-a)^2)
nlm(f, c(10,10), a = c(3,5))
f <- function(x, a)
{
 res <- sum((x-a)^2)
 attr(res, "gradient") <- 2*(x-a)
 res
}
nlm(f, c(10,10), a = c(3,5))

more examples, including the use of derivatives.
Not run: demo(nlm)
```

## Description

Unconstrained and box-constrained optimization using PORT routines.

For historical compatibility.

## Usage

```
nlminb(start, objective, gradient = NULL, hessian = NULL, ...,
 scale = 1, control = list(), lower = -Inf, upper = Inf)
```

### Arguments

|                                         |                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>start</code>                      | numeric vector, initial values for the parameters to be optimized.                                                                                                                                                                                                                                                                           |
| <code>objective</code>                  | Function to be minimized. Must return a scalar value. The first argument to <code>objective</code> is the vector of parameters to be optimized, whose initial values are supplied through <code>start</code> . Further arguments (fixed during the course of the optimization) to <code>objective</code> may be specified as well (see ...). |
| <code>gradient</code>                   | Optional function that takes the same arguments as <code>objective</code> and evaluates the gradient of <code>objective</code> at its first argument. Must return a vector as long as <code>start</code> .                                                                                                                                   |
| <code>hessian</code>                    | Optional function that takes the same arguments as <code>objective</code> and evaluates the hessian of <code>objective</code> at its first argument. Must return a square matrix of order <code>length(start)</code> . Only the lower triangle is used.                                                                                      |
| <code>...</code>                        | Further arguments to be supplied to <code>objective</code> .                                                                                                                                                                                                                                                                                 |
| <code>scale</code>                      | See PORT documentation (or leave alone).                                                                                                                                                                                                                                                                                                     |
| <code>control</code>                    | A list of control parameters. See below for details.                                                                                                                                                                                                                                                                                         |
| <code>lower</code> , <code>upper</code> | vectors of lower and upper bounds, replicated to be as long as <code>start</code> . If unspecified, all parameters are assumed to be unconstrained.                                                                                                                                                                                          |

### Details

Any names of `start` are passed on to `objective` and where applicable, `gradient` and `hessian`. The parameter vector will be coerced to double.

The PORT documentation is at <http://netlib.bell-labs.com/cm/cs/cstr/153.pdf>.

The parameter vector passed to `objective`, `gradient` and `hessian` has special semantics and is shared between calls. The functions should not copy it.

If any of the functions returns NA or NaN the internal code could infinite-loop in R prior to 2.15.2: this is now an error for the gradient and Hessian, and such values for function evaluation are replaced by +Inf with a warning.

### Value

A list with components:

|                          |                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>par</code>         | The best set of parameters found.                                                                                             |
| <code>objective</code>   | The value of <code>objective</code> corresponding to <code>par</code> .                                                       |
| <code>convergence</code> | An integer code. 0 indicates successful convergence.                                                                          |
| <code>message</code>     | A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation. |
| <code>iterations</code>  | Number of iterations performed.                                                                                               |
| <code>evaluations</code> | Number of objective function and gradient function evaluations                                                                |

### Control parameters

Possible names in the `control` list and their default values are:

`eval.max` Maximum number of evaluations of the objective function allowed. Defaults to 200.

`iter.max` Maximum number of iterations allowed. Defaults to 150.

**trace** The value of the objective function and the parameters is printed every trace'th iteration.  
 Defaults to 0 which indicates no trace information is to be printed.

**abs.tol** Absolute tolerance. Defaults to 0 so the absolute convergence test is not used. If the objective function is known to be non-negative, the previous default of 1e-20 would be more appropriate.

**rel.tol** Relative tolerance. Defaults to 1e-10.

**x.tol** X tolerance. Defaults to 1.5e-8.

**xf.tol** false convergence tolerance. Defaults to 2.2e-14.

**step.min, step.max** Minimum and maximum step size. Both default to 1..

**sing.tol** singular convergence tolerance; defaults to rel.tol.

**scale.init ...**

**diff.g** an estimated bound on the relative error in the objective function value.

### Author(s)

[optim](#) (which is preferred) and [nlm](#).

[optimize](#) for one-dimensional minimization and [constrOptim](#) for constrained optimization.

### Examples

```

x <- rnbinom(100, mu = 10, size = 10)
hdev <- function(par)
 -sum(dnbinom(x, mu = par[1], size = par[2], log = TRUE))
nlminb(c(9, 12), hdev)
nlminb(c(20, 20), hdev, lower = 0, upper = Inf)
nlminb(c(20, 20), hdev, lower = 0.001, upper = Inf)

slightly modified from the S-PLUS help page for nlminb
this example minimizes a sum of squares with known solution y
sumsq <- function(x, y) {sum((x-y)^2)}
y <- rep(1,5)
x0 <- rnorm(length(y))
nlminb(start = x0, sumsq, y = y)
now use bounds with a y that has some components outside the bounds
y <- c(0, 2, 0, -2, 0)
nlminb(start = x0, sumsq, lower = -1, upper = 1, y = y)
try using the gradient
sumsq.g <- function(x, y) 2*(x-y)
nlminb(start = x0, sumsq, sumsq.g,
 lower = -1, upper = 1, y = y)
now use the hessian, too
sumsq.h <- function(x, y) diag(2, nrow = length(x))
nlminb(start = x0, sumsq, sumsq.g, sumsq.h,
```

```

lower = -1, upper = 1, y = y)

Rest lifted from optim help page

fr <- function(x) { ## Rosenbrock Banana function
 x1 <- x[1]
 x2 <- x[2]
 100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) { ## Gradient of fr
 x1 <- x[1]
 x2 <- x[2]
 c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
 200 * (x2 - x1 * x1))
}
nlminb(c(-1.2,1), fr)
nlminb(c(-1.2,1), fr, grr)

flb <- function(x)
 { p <- length(x); sum(c(1, rep(4, p-1)) * (x - c(1, x[-p])^2)^2) }
25-dimensional box constrained
par[24] is *not* at boundary
nlminb(rep(3, 25), flb, lower = rep(2, 25), upper = rep(4, 25))
trying to use a too small tolerance:
r <- nlminb(rep(3, 25), flb, control = list(rel.tol = 1e-16))
stopifnot(grepl("rel.tol", r$message))

```

**nls***Nonlinear Least Squares***Description**

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

**Usage**

```
nls(formula, data, start, control, algorithm,
 trace, subset, weights, na.action, model,
 lower, upper, ...)
```

**Arguments**

- |                |                                                                                                                                                                            |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>formula</b> | a nonlinear model <b>formula</b> including variables and parameters. Will be coerced to a formula if necessary.                                                            |
| <b>data</b>    | an optional data frame in which to evaluate the variables in <b>formula</b> and <b>weights</b> . Can also be a list or an environment, but not a matrix.                   |
| <b>start</b>   | a named list or named numeric vector of starting estimates. When <b>start</b> is missing, a very cheap guess for <b>start</b> is tried (if <b>algorithm</b> != "plinear"). |
| <b>control</b> | an optional list of control settings. See <b>nls.control</b> for the names of the settable control values and their effect.                                                |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| algorithm     | character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port library – see the references.                                                                                                                                                                                    |
| trace         | logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares and the parameter values are printed at the conclusion of each iteration. When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares. |
| subset        | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                                                               |
| weights       | an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.                                                                                                                                                                                                                                                                                                                                                                          |
| na.action     | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of <a href="#">options</a> , and is <a href="#">na.fail</a> if that is unset. The 'factory-fresh' default is <a href="#">na.omit</a> . Value <a href="#">na.exclude</a> can be useful.                                                                                                                                                                             |
| model         | logical. If true, the model frame is returned as part of the object. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                  |
| lower , upper | vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.                                                                                                                                                                                                                               |
| ...           | Additional optional arguments. None are used at present.                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Details

An `nls` object is a type of fitted model object. It has methods for the generic functions [anova](#), [coef](#), [confint](#), [deviance](#), [df.residual](#), [fitted](#), [formula](#), [logLik](#), [predict](#), [print](#), [profile](#), [residuals](#), [summary](#), [vcov](#) and [weights](#).

Variables in `formula` (and `weights` if not missing) are looked for first in `data`, then the environment of `formula` and finally along the search path. Functions in `formula` are searched for first in the environment of `formula` and then along the search path.

Arguments `subset` and `na.action` are supported only when all the variables in the formula taken from `data` are of the same length: other cases give a warning.

Note that the [anova](#) method does not check that the models are nested: this cannot easily be done automatically, so use with care.

## Value

A list of

|             |                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| m           | an <code>nlsModel</code> object incorporating the model.                                                                                                                     |
| data        | the expression that was passed to <code>nls</code> as the <code>data</code> argument. The actual data values are present in the environment of the <code>m</code> component. |
| call        | the matched call with several components, notably <code>algorithm</code> .                                                                                                   |
| na.action   | the "na.action" attribute (if any) of the model frame.                                                                                                                       |
| dataClasses | the "dataClasses" attribute (if any) of the "terms" attribute of the model frame.                                                                                            |

model            if `model` = TRUE, the model frame.  
 weights        if `weights` is supplied, the weights.  
 convInfo        a list with convergence information.  
 control        the control list used, see the `control` argument.  
 convergence, message  
                   for an `algorithm` = "port" fit only, a convergence code (0 for convergence) and message.  
                   To use these is *deprecated*, as they are available from `convInfo` now.

## Warning

### Do not use nls on artificial "zero-residual" data.

The `nls` function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

$$y = f(x, \theta) + \epsilon$$

(with `var(eps) > 0`). It fails to indicate convergence on data of the form

$$y = f(x, \theta)$$

because the criterion amounts to comparing two components of the round-off error. If you wish to test `nls` on artificial data please add a noise component, as shown in the example below.

The `algorithm` = "port" code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.

## Note

Setting `warnOnly` = TRUE in the `control` argument (see `nls.control`) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, *but not for inference*.

## Examples

```

require(graphics)

DNase1 <- subset(DNase, Run == 1)

using a selfStart model
fm1DNase1 <- nls(density ~ SSlogis(log(conc), Asym, xmid, scal), DNase1)
summary(fm1DNase1)
the coefficients only:
coef(fm1DNase1)
including their SE, etc:
coef(summary(fm1DNase1))

using conditional linearity
fm2DNase1 <- nls(density ~ 1/(1 + exp((xmid - log(conc))/scal)),
 data = DNase1,
 start = list(xmid = 0, scal = 1),
 algorithm = "plinear")
summary(fm2DNase1)

without conditional linearity
fm3DNase1 <- nls(density ~ Asym/(1 + exp((xmid - log(conc))/scal)),
 data = DNase1,
 start = list(Asym = 3, xmid = 0, scal = 1))
summary(fm3DNase1)

using Ports nl2sol algorithm
fm4DNase1 <- nls(density ~ Asym/(1 + exp((xmid - log(conc))/scal)),
 data = DNase1,
 start = list(Asym = 3, xmid = 0, scal = 1),
 algorithm = "port")
summary(fm4DNase1)

weighted nonlinear regression
Treated <- Puromycin[Puromycin$state == "treated",]
weighted.MM <- function(resp, conc, Vm, K)
{
 ## Purpose: exactly as white book p. 451 -- RHS for nls()
 ## Weighted version of Michaelis-Menten model
 ##
 ## -----
 ## Arguments: y, x and the two parameters (see book)
 ## -----
 ## Author: Martin Maechler, Date: 23 Mar 2001

 pred <- (Vm * conc)/(K + conc)
 (resp - pred) / sqrt(pred)
}

Pur.wt <- nls(~ weighted.MM(rate, conc, Vm, K), data = Treated,
 start = list(Vm = 200, K = 0.1))
summary(Pur.wt)

Passing arguments using a list that can not be coerced to a data.frame
lisTreat <- with(Treated,
 list(conc1 = conc[1], conc.1 = conc[-1], rate = rate))

```

```

weighted.MM1 <- function(resp, conc1, conc.1, Vm, K)
{
 conc <- c(conc1, conc.1)
 pred <- (Vm * conc)/(K + conc)
 (resp - pred) / sqrt(pred)
}
Pur.wt1 <- nls(~ weighted.MM1(rate, conc1, conc.1, Vm, K),
 data = lisTreat, start = list(Vm = 200, K = 0.1))
stopifnot(all.equal(coef(Pur.wt), coef(Pur.wt1)))

Chambers and Hastie (1992) Statistical Models in S (p. 537):
If the value of the right side [of formula] has an attribute called
gradient this should be a matrix with the number of rows equal
to the length of the response and one column for each parameter.

weighted.MM.grad <- function(resp, conc1, conc.1, Vm, K)
{
 conc <- c(conc1, conc.1)

 K.conc <- K+conc
 dy.dV <- conc/K.conc
 dy.dK <- -Vm*dy.dV/K.conc
 pred <- Vm*dy.dV
 pred.5 <- sqrt(pred)
 dev <- (resp - pred) / pred.5
 Ddev <- -0.5*(resp+pred)/(pred.5*pred)
 attr(dev, "gradient") <- Ddev * cbind(Vm = dy.dV, K = dy.dK)
 dev
}

Pur.wt.grad <- nls(~ weighted.MM.grad(rate, conc1, conc.1, Vm, K),
 data = lisTreat, start = list(Vm = 200, K = 0.1))

rbind(coef(Pur.wt), coef(Pur.wt1), coef(Pur.wt.grad))

In this example, there seems no advantage to providing the gradient.
In other cases, there might be.

The two examples below show that you can fit a model to
artificial data with noise but not to artificial data
without noise.
x <- 1:10
y <- 2*x + 3 # perfect fit
yeps <- y + rnorm(length(y), sd = 0.01) # added noise
nls(yeps ~ a + b*x, start = list(a = 0.12345, b = 0.54321))
Not run:
terminates in an error, because convergence cannot be confirmed:
nls(y ~ a + b*x, start = list(a = 0.12345, b = 0.54321))

End(Not run)

the nls() internal cheap guess for starting values can be sufficient:

x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x))

```

```

plot(x,y, main = "nls(*), data, true function and fit, n=100")
curve(100 + 10 * exp(x / 2), col = 4, add = TRUE)
lines(x, predict(nlmod), col = 2)

The muscle dataset in MASS is from an experiment on muscle
contraction on 21 animals. The observed variables are Strip
(identifier of muscle), Conc (CaCl concentration) and Length
(resulting length of muscle section).
utils::data(muscle, package = "MASS")

The non linear model considered is
Length = alpha + beta*exp(-Conc/theta) + error
where theta is constant but alpha and beta may vary with Strip.

with(muscle, table(Strip)) # 2, 3 or 4 obs per strip

We first use the plinear algorithm to fit an overall model,
ignoring that alpha and beta might vary with Strip.

musc.1 <- nls(Length ~ cbind(1, exp(-Conc/th)), muscle,
 start = list(th = 1), algorithm = "plinear")
summary(musc.1)

Then we use nls indexing feature for parameters in non-linear
models to use the conventional algorithm to fit a model in which
alpha and beta vary with Strip. The starting values are provided
by the previously fitted model.
Note that with indexed parameters, the starting values must be
given in a list (with names):
b <- coef(musc.1)
musc.2 <- nls(Length ~ a[Strip] + b[Strip]*exp(-Conc/th), muscle,
 start = list(a = rep(b[2], 21), b = rep(b[3], 21), th = b[1]))
summary(musc.2)

```

**nls.control***Control the Iterations in nls***Description**

Allow the user to set some characteristics of the `nls` nonlinear least squares algorithm.

**Usage**

```
nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024,
 printEval = FALSE, warnOnly = FALSE)
```

**Arguments**

|                      |                                                                         |
|----------------------|-------------------------------------------------------------------------|
| <code>maxiter</code> | A positive integer specifying the maximum number of iterations allowed. |
|----------------------|-------------------------------------------------------------------------|

|                        |                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tol</code>       | A positive numeric value specifying the tolerance level for the relative offset convergence criterion.                                                                                                                                                                                                                                                         |
| <code>minFactor</code> | A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.                                                 |
| <code>printEval</code> | a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.                                                                                                                                                                                                                                      |
| <code>warnOnly</code>  | a logical specifying whether <code>nls()</code> should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of <code>maxiter</code> iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below <code>minFactor</code> . |

### Value

A list with exactly five components:

```
maxiter
tol
minFactor
printEval
warnOnly
```

with meanings as explained under ‘Arguments’.

```

**NLSstAsymptotic***Fit the Asymptotic Regression Model***Description**

Fits the asymptotic regression model, in the form  $b0 + b1 * (1 - \exp(-\exp(lrc) * x))$  to the xy data. This can be used as a building block in determining starting estimates for more complicated models.

**Usage**

```
NLSstAsymptotic(xy)
```

**Arguments**

|    |                       |
|----|-----------------------|
| xy | a sortedXyData object |
|----|-----------------------|

**Value**

A numeric value of length 3 with components labelled b0, b1, and lrc. b0 is the estimated intercept on the y-axis, b1 is the estimated difference between the asymptote and the y-intercept, and lrc is the estimated logarithm of the rate constant.

**Author(s)**

José Pinheiro and Douglas Bates

**Examples**

```
Lob.329 <- Loblolly[Loblolly$Seed == "329",]
print(NLSstAsymptotic(sortedXyData(expression(age),
 expression(height),
 Lob.329)), digits = 3)
```

**NLSstClosestX***Inverse Interpolation***Description**

Use inverse linear interpolation to approximate the x value at which the function represented by xy is equal to yval.

**Usage**

```
NLSstClosestX(xy, yval)
```

**Arguments**

|                   |                                |
|-------------------|--------------------------------|
| <code>xy</code>   | a sortedXyData object          |
| <code>yval</code> | a numeric value on the y scale |

**Value**

A single numeric value on the x scale.

**Author(s)**

José Pinheiro and Douglas Bates

NLSstClosestX(DN.srt, 1.0)
```

**NLSstLfAsymptote**

*Horizontal Asymptote on the Left Side*

**Description**

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of x) of the graph of y versus x from the `xy` object. Primarily used within `initial` functions for self-starting nonlinear regression models.

**Usage**

```
NLSstLfAsymptote(xy)
```

**Arguments**

|                 |                       |
|-----------------|-----------------------|
| <code>xy</code> | a sortedXyData object |
|-----------------|-----------------------|

**Value**

A single numeric value estimating the horizontal asymptote for small x.

**Author(s)**

José Pinheiro and Douglas Bates

---

## Description

Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of  $x$ ) of the graph of  $y$  versus  $x$  from the  $xy$  object. Primarily used within `initial` functions for self-starting nonlinear regression models.

## Usage

```
NLSstRtAsymptote(xy)
```

## Arguments

`xy`                  a `sortedXyData` object

## Value

A single numeric value estimating the horizontal asymptote for large  $x$ .

## Author(s)

José Pinheiro and Douglas Bates

## See Also

[sortedXyData](#), [NLSstClosestX](#), [NLSstRtAsymptote](#), [selfStart](#)

## Examples

```
DNase.2 <- DNase[DNase$Run == "2",]
DN.srt <- sortedXyData(expression(log(conc)), expression(density), DNase.2)
NLSstRtAsymptote(DN.srt)
```

**nobs***Extract the Number of Observations from a Fit.*

## Description

Extract the number of ‘observations’ from a model fit. This is principally intended to be used in computing BIC (see [AIC](#)).

## Usage

```
nobs(object, ...)

Default S3 method:
nobs(object, use.fallback = FALSE, ...)
```

## Arguments

|                           |                                                                     |
|---------------------------|---------------------------------------------------------------------|
| <code>object</code>       | A fitted model object.                                              |
| <code>use.fallback</code> | logical: should fallback methods be used to try to guess the value? |
| <code>...</code>          | Further arguments to be passed to methods.                          |

## Details

This is a generic function, with an S4 generic in package **stats4**. There are methods in this package for objects of classes "**lm**", "**glm**", "**nls**" and "**logLik**", as well as a default method (which throws an error, unless `use.fallback = TRUE` when it looks for `weights` and `residuals` components – use with care!).

The main usage is in determining the appropriate penalty for BIC, but `nobs` is also used by the stepwise fitting methods `step`, `add1` and `drop1` as a quick check that different fits have been fitted to the same set of data (and not, say, that further rows have been dropped because of NAs in the new predictors).

For `lm`, `glm` and `nls` fits, observations with zero weight are not included.

## Value

A single number, normally an integer. Could be NA.

## See Also

[AIC](#).

**Normal***The Normal Distribution***Description**

Density, distribution function, quantile function and random generation for the normal distribution with mean equal to `mean` and standard deviation equal to `sd`.

**Usage**

```
dnorm(x, mean = 0, sd = 1, log = FALSE)
pnorm(q, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
qnorm(p, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
rnorm(n, mean = 0, sd = 1)
```

**Arguments**

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                      |
| <code>p</code>          | vector of probabilities.                                                                                  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>mean</code>       | vector of means.                                                                                          |
| <code>sd</code>         | vector of standard deviations.                                                                            |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                         |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ otherwise, $P[X > x]$ .                       |

**Details**

If `mean` or `sd` are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-(x-\mu)^2/2\sigma^2}$$

where  $\mu$  is the mean of the distribution and  $\sigma$  the standard deviation.

`qnorm` is based on Wichura's algorithm AS 241 which provides precise results up to about 16 digits.

**Value**

`dnorm` gives the density, `pnorm` gives the distribution function, `qnorm` gives the quantile function, and `rnorm` generates random deviates.

The length of the result is determined by `n` for `rnorm`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

## Source

For `pnorm`, based on

Cody, W. D. (1993) Algorithm 715: SPECFUN – A portable FORTRAN package of special function routines and test drivers. *ACM Transactions on Mathematical Software* **19**, 22–32.

For `qnorm`, the code is a C translation of

Wichura, M. J. (1988) Algorithm AS 241: The percentage points of the normal distribution. *Applied Statistics*, **37**, 477–484.

For `rnorm`, see [RNG](#) for how to select the algorithm and for references to the supplied methods.

## Examples

```
require(graphics)

dnorm(0) == 1/sqrt(2*pi)
dnorm(1) == exp(-1/2)/sqrt(2*pi)
dnorm(1) == 1/sqrt(2*pi*exp(1))

Using "log = TRUE" for an extended range :
par(mfrow = c(2,1))
plot(function(x) dnorm(x, log = TRUE), -60, 50,
 main = "log { Normal density }")
curve(log(dnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("dnorm(x, log=TRUE)", adj = 0)
mtext("log(dnorm(x))", col = "red", adj = 1)

plot(function(x) pnorm(x, log.p = TRUE), -50, 10,
 main = "log { Normal Cumulative }")
curve(log(pnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("pnorm(x, log=TRUE)", adj = 0)
mtext("log(pnorm(x))", col = "red", adj = 1)

if you want the so-called error function
erf <- function(x) 2 * pnorm(x * sqrt(2)) - 1
(see Abramowitz and Stegun 29.2.29)
and the so-called complementary error function
erfc <- function(x) 2 * pnorm(x * sqrt(2), lower = FALSE)
and the inverses
erfinv <- function (x) qnorm((1 + x)/2)/sqrt(2)
erfcinv <- function (x) qnorm(x/2, lower = FALSE)/sqrt(2)
```

---

|              |                                         |
|--------------|-----------------------------------------|
| numericDeriv | <i>Evaluate Derivatives Numerically</i> |
|--------------|-----------------------------------------|

---

## Description

numericDeriv numerically evaluates the gradient of an expression.

## Usage

```
numericDeriv(expr, theta, rho = parent.frame(), dir = 1.0)
```

## Arguments

|       |                                                                                               |
|-------|-----------------------------------------------------------------------------------------------|
| expr  | The expression to be differentiated. The value of this expression should be a numeric vector. |
| theta | A character vector of names of numeric variables used in expr.                                |
| rho   | An environment containing all the variables needed to evaluate expr.                          |
| dir   | A numeric vector of directions to use for the finite differences.                             |

## Details

This is a front end to the C function `numeric_deriv`, which is described in *Writing R Extensions*.

The numeric variables must be of type `real` and not `integer`.

## Value

The value of `eval(expr, envir = rho)` plus a matrix attribute called `gradient`. The columns of this matrix are the derivatives of the value with respect to the variables listed in `theta`.

## Author(s)

Saikat DebRoy <[saikat@stat.wisc.edu](mailto:saikat@stat.wisc.edu)>

## Examples

```
myenv <- new.env()
assign("mean", 0., envir = myenv)
assign("sd", 1., envir = myenv)
assign("x", seq(-3., 3., len = 31), envir = myenv)
numericDeriv(quote(pnorm(x, mean, sd)), c("mean", "sd"), myenv)
```

|--------|---------------------------------------------|
| offset | <i>Include an Offset in a Model Formula</i> |
|--------|---------------------------------------------|

---

## Description

An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

## Usage

```
offset(object)
```

## Arguments

|        |                                           |
|--------|-------------------------------------------|
| object | An offset to be included in a model frame |
|--------|-------------------------------------------|

## Details

There can be more than one offset in a model formula, but - is not supported for offset terms (and is equivalent to +).

## Value

The input value.

## See Also

[model.offset](#), [model.frame](#).

For examples see [glm](#) and [Insurance](#) in package **MASS**.

|-------------|-------------------------------------------------|
| oneway.test | <i>Test for Equal Means in a One-Way Layout</i> |
|-------------|-------------------------------------------------|

---

## Description

Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

## Usage

```
oneway.test(formula, data, subset, na.action, var.equal = FALSE)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the sample values and <code>rhs</code> the corresponding groups.                                                                                                                                                                                                                                           |
| <code>data</code>      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                           |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                                                                                                                   |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                                                                                                                                                                           |
| <code>var.equal</code> | a logical variable indicating whether to treat the variances in the samples as equal. If <code>TRUE</code> , then a simple F test for the equality of means in a one-way analysis of variance is performed. If <code>FALSE</code> , an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples. |

### Value

A list with class "htest" containing the following components:

|                        |                                                                                          |
|------------------------|------------------------------------------------------------------------------------------|
| <code>statistic</code> | the value of the test statistic.                                                         |
| <code>parameter</code> | the degrees of freedom of the exact or approximate F distribution of the test statistic. |
| <code>p.value</code>   | the p-value of the test.                                                                 |
| <code>method</code>    | a character string indicating the test performed.                                        |
| <code>data.name</code> | a character string giving the names of the data.                                         |

### Examples

```
Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
which gives the same result as
anova(lm(extra ~ group, data = sleep))
```

**optim***General-purpose Optimization***Description**

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

**Usage**

```
optim(par, fn, gr = NULL, ...,
 method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN",
 "Brent"),
 lower = -Inf, upper = Inf,
 control = list(), hessian = FALSE)

optimHess(par, fn, gr = NULL, ..., control = list())
```

**Arguments**

|                                         |                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>par</code>                        | Initial values for the parameters to be optimized over.                                                                                                                                                                                                                                                              |
| <code>fn</code>                         | A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.                                                                                                                                                  |
| <code>gr</code>                         | A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is <code>NULL</code> , a finite-difference approximation will be used.<br>For the "SANN" method it specifies a function to generate a new candidate point. If it is <code>NULL</code> a default Gaussian Markov kernel is used. |
| <code>...</code>                        | Further arguments to be passed to <code>fn</code> and <code>gr</code> .                                                                                                                                                                                                                                              |
| <code>method</code>                     | The method to be used. See ‘Details’.                                                                                                                                                                                                                                                                                |
| <code>lower</code> , <code>upper</code> | Bounds on the variables for the "L-BFGS-B" method, or bounds in which to <i>search</i> for method "Brent".                                                                                                                                                                                                           |
| <code>control</code>                    | A list of control parameters. See ‘Details’.                                                                                                                                                                                                                                                                         |
| <code>hessian</code>                    | Logical. Should a numerically differentiated Hessian matrix be returned?                                                                                                                                                                                                                                             |

**Details**

Note that arguments after `...` must be matched exactly.

By default `optim` performs minimization, but it will maximize if `control$fnyscale` is negative. `optimHess` is an auxiliary function to compute the Hessian at a later stage if `hessian = TRUE` was forgotten.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.

Method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.

Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd *et. al.* (1995) which allows *box constraints*, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated-annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to `temp / log(((t-1) %/% tmax)*tmax + exp(1))`, where `t` is the current iteration step and `temp` and `tmax` are specifiable via `control`, see below. Note that the "SANN" method depends critically on the settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Method "Brent" is for one-dimensional problems only, using `optimize()`. It can be useful in cases where `optim()` is used inside other functions where only `method` can be specified, such as in `mle` from package `stats4`.

Function `fn` can return `NA` or `Inf` if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of `fn`. (Except for method "L-BFGS-B" where the values should always be finite.)

`optim` can be used recursively, and for a single parameter as well as many. It also accepts a zero-length `par`, and just evaluates the function with that argument.

The `control` argument is a list that can supply any of the following components:

`trace` Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)

`fnscale` An overall scaling to be applied to the value of `fn` and `gr` during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on `fn(par)/fnscale`.

`parscale` A vector of scaling values for the parameters. Optimization is performed on `par/parscale` and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value. Not used (nor needed) for `method = "Brent"`.

`ndeps` A vector of step sizes for the finite-difference approximation to the gradient, on `par/parscale` scale. Defaults to `1e-3`.

`maxit` The maximum number of iterations. Defaults to 100 for the derivative-based methods, and 500 for "Nelder-Mead".

For "SANN" `maxit` gives the total number of function evaluations: there is no other stopping criterion. Defaults to 10000.

`abstol` The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.

**reldtol** Relative convergence tolerance. The algorithm stops if it is unable to reduce the value by a factor of `reldtol * (abs(val) + reldtol)` at a step. Defaults to `sqrt(.Machine$double.eps)`, typically about `1e-8`.

**alpha, beta, gamma** Scaling parameters for the "Nelder–Mead" method. `alpha` is the reflection factor (default 1.0), `beta` the contraction factor (0.5) and `gamma` the expansion factor (2.0).

**REPORT** The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if `control$trace` is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or every 100 temperatures for "SANN".

**type** for the conjugate-gradients method. Takes value 1 for the Fletcher–Reeves update, 2 for Polak–Ribiere and 3 for Beale–Sorenson.

**lmm** is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method. It defaults to 5.

**factr** controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduction in the objective is within this factor of the machine tolerance. Default is `1e7`, that is a tolerance of about `1e-8`.

**pgtol** helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected gradient in the current search direction. This defaults to zero, when the check is suppressed.

**temp** controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults to 10.

**tmax** is the number of function evaluations at each temperature for the "SANN" method. Defaults to 10.

Any names given to `par` will be copied to the vectors passed to `fn` and `gr`. Note that no other attributes of `par` are copied over.

The parameter vector passed to `fn` has special semantics and may be shared between calls: the function should not change or copy it.

## Value

For `optim`, a list with components:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>par</code>         | The best set of parameters found.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>value</code>       | The value of <code>fn</code> corresponding to <code>par</code> .                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>counts</code>      | A two-element integer vector giving the number of calls to <code>fn</code> and <code>gr</code> respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to <code>fn</code> to compute a finite-difference approximation to the gradient.                                                                                                                                                                                                            |
| <code>convergence</code> | An integer code. 0 indicates successful completion (which is always the case for "SANN" and "Brent"). Possible error codes are<br>1 indicates that the iteration limit <code>maxit</code> had been reached.<br>10 indicates degeneracy of the Nelder–Mead simplex.<br>51 indicates a warning from the "L-BFGS-B" method; see component <code>message</code> for further details.<br>52 indicates an error from the "L-BFGS-B" method; see component <code>message</code> for further details. |
| <code>message</code>     | A character string giving any additional information returned by the optimizer, or <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>hessian</code>     | Only if argument <code>hessian</code> is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.                                                                                                                                                                                                                                                                 |

For `optimHess`, the description of the `hessian` component applies.

### Note

`optim` will work with one-dimensional pars, but the default method does not work well (and will warn). Method "Brent" uses `optimize` and needs bounds to be available; "BFGS" often works well enough if not.

### Source

The code for methods "Nelder-Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file 'opt/lbfsgs\_bcm.shar': another version is in 'toms/778').

The code for method "SANN" was contributed by A. Trapletti.

**optimize***One Dimensional Optimization***Description**

The function `optimize` searches the interval from `lower` to `upper` for a minimum or maximum of the function `f` with respect to its first argument.

`optimise` is an alias for `optimize`.

**Usage**

```

optimize(f = , interval = , ... , lower = min(interval),
 upper = max(interval), maximum = FALSE,
 tol = .Machine$double.eps^0.25)
optimise(f = , interval = , ... , lower = min(interval),
 upper = max(interval), maximum = FALSE,
 tol = .Machine$double.eps^0.25)

```

**Arguments**

|                       |                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>        | the function to be optimized. The function is either minimized or maximized over its first argument depending on the value of <code>maximum</code> . |
| <code>interval</code> | a vector containing the end-points of the interval to be searched for the minimum.                                                                   |
| <code>...</code>      | additional named or unnamed arguments to be passed to <code>f</code> .                                                                               |
| <code>lower</code>    | the lower end point of the interval to be searched.                                                                                                  |
| <code>upper</code>    | the upper end point of the interval to be searched.                                                                                                  |
| <code>maximum</code>  | logical. Should we maximize or minimize (the default)?                                                                                               |
| <code>tol</code>      | the desired accuracy.                                                                                                                                |

**Details**

Note that arguments after `...` must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation, and was designed for use with continuous functions. Convergence is never much slower than that for a Fibonacci search. If `f` has a continuous second derivative which is positive at the minimum (which is not at `lower` or `upper`), then convergence is superlinear, and usually of the order of about 1.324.

The function  $f$  is never evaluated at two points closer together than  $\epsilon|x_0| + (tol/3)$ , where  $\epsilon$  is approximately  $\text{sqrt}(\text{Machine\$double.eps})$  and  $x_0$  is the final abscissa  $\text{optimize()\$minimum}$ . If  $f$  is a unimodal function and the computed values of  $f$  are always unimodal when separated by at least  $\epsilon|x| + (tol/3)$ , then  $x_0$  approximates the abscissa of the global minimum of  $f$  on the interval `lower,upper` with an error less than  $\epsilon|x_0| + tol$ .

If  $f$  is not unimodal, then  $\text{optimize()}$  may approximate a local, but perhaps non-global, minimum to the same accuracy.

The first evaluation of  $f$  is always at  $x_1 = a + (1 - \phi)(b - a)$  where  $(a, b) = (\text{lower}, \text{upper})$  and  $\phi = (\sqrt{5} - 1)/2 = 0.61803\dots$  is the golden section ratio. Almost always, the second evaluation is at  $x_2 = a + \phi(b - a)$ . Note that a local minimum inside  $[x_1, x_2]$  will be found as solution, even when  $f$  is constant in there, see the last example.

$f$  will be called as  $f(x, \dots)$  for a numeric value of  $x$ .

The argument passed to  $f$  has special semantics and used to be shared between calls. The function should not copy it.

## Value

A list with components `minimum` (or `maximum`) and `objective` which give the location of the minimum (or maximum) and the value of the function at that point.

## Source

A C translation of Fortran code <http://www.netlib.org/fmm/fmin.f> (author(s) unstated) based on the Algol 60 procedure `localmin` given in the reference.

## References

## Examples

```
require(graphics)

f <- function (x, a) (x - a)^2
xmin <- optimize(f, c(0, 1), tol = 0.0001, a = 1/3)
xmin

See where the function is evaluated:
optimize(function(x) x^2*(print(x)-1), lower = 0, upper = 10)

"wrong" solution with unlucky interval and piecewise constant f():
f <- function(x) ifelse(x > -1, ifelse(x < 4, exp(-1/abs(x - 1)), 10), 10)
fp <- function(x) { print(x); f(x) }

plot(f, -2,5, ylim = 0:1, col = 2)
optimize(fp, c(-4, 20)) # doesnt see the minimum
optimize(fp, c(-7, 20)) # ok
```

---

**order.dendrogram***Ordering or Labels of the Leaves in a Dendrogram*

---

## Description

These functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.

## Usage

```
order.dendrogram(x)

S3 method for class dendrogram
labels(object, ...)
```

## Arguments

|                        |                                                    |
|------------------------|----------------------------------------------------|
| <code>x, object</code> | a dendrogram (see <a href="#">as.dendrogram</a> ). |
| <code>...</code>       | additional arguments                               |

## Details

The indices or labels for the leaves in left to right order are retrieved.

## Value

A vector with length equal to the number of leaves in the dendrogram is returned. From `r <- order.dendrogram()`, each element is the index into the original data (from which the dendrogram was computed).

## Author(s)

R. Gentleman (`order.dendrogram`) and Martin Maechler (`labels.dendrogram`).

## See Also

[reorder](#), [dendrogram](#).

## Examples

```
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same :
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) ## in this case the same as
stopifnot(identical(labels(d2),
rownames(USArrests)[order.dendrogram(d2)]))
```

---

**p.adjust***Adjust P-values for Multiple Comparisons*

---

**Description**

Given a set of p-values, returns p-values adjusted using one of several methods.

**Usage**

```
p.adjust(p, method = p.adjust.methods, n = length(p))

p.adjust.methods
c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
"fdr", "none")
```

**Arguments**

|               |                                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>p</b>      | numeric vector of p-values (possibly with <b>NA</b> s). Any other R is coerced by <b>as.numeric</b> .                       |
| <b>method</b> | correction method                                                                                                           |
| <b>n</b>      | number of comparisons, must be at least <b>length(p)</b> ; only set this (to non-default) when you know what you are doing! |

**Details**

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH" or its alias "fdr"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the **p.adjust.methods** vector for the benefit of methods that need to have the method as an option and pass it on to **p.adjust**.

The first four methods are designed to give strong control of the family-wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm's method, which is also valid under arbitrary assumptions.

Hochberg's and Hommel's methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel's method is more powerful than Hochberg's, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" (aka "fdr") and "BY" method of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others.

Note that you can set **n** larger than **length(p)** which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

**Value**

A numeric vector of corrected p-values (of the same length as **p**, with names copied from **p**).

## See Also

`pairwise.*` functions such as [pairwise.t.test](#).

## Examples

```
require(graphics)

set.seed(123)
x <- rnorm(50, mean = c(rep(0, 25), rep(3, 25)))
p <- 2*pnorm(sort(-abs(x)))

round(p, 3)
round(p.adjust(p), 3)
round(p.adjust(p, "BH"), 3)

or all of them at once (dropping the "fdr" alias):
p.adjust.M <- p.adjust.methods[p.adjust.methods != "fdr"]
p.adj <- sapply(p.adjust.M, function(meth) p.adjust(p, meth))
p.adj.60 <- sapply(p.adjust.M, function(meth) p.adjust(p, meth, n = 60))
stopifnot(identical(p.adj[,"none"], p), p.adj <= p.adj.60)
round(p.adj, 3)
or a bit nicer:
noquote(apply(p.adj, 2, format.pval, digits = 3))

and a graphic:
matplot(p, p.adj, ylab="p.adjust(p, meth)", type = "l", asp = 1, lty = 1:6,
 main = "P-value adjustments")
legend(0.7, 0.6, p.adjust.M, col = 1:6, lty = 1:6)

Can work with NAs:
```

```
pN <- p; iN <- c(46, 47); pN[iN] <- NA
pN.a <- sapply(p.adjust.M, function(meth) p.adjust(pN, meth))
The smallest 20 P-values all affected by the NAs :
round((pN.a / p.adj)[1:20,] , 4)
```

**pairwise.prop.test**      *Pairwise comparisons for proportions*

## Description

Calculate pairwise comparisons between pairs of proportions with correction for multiple testing

## Usage

```
pairwise.prop.test(x, n, p.adjust.method = p.adjust.methods, ...)
```

## Arguments

- x                  Vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.
- n                  Vector of counts of trials; ignored if x is a matrix.
- p.adjust.method      Method for adjusting p values (see [p.adjust](#))
- ...                Additional arguments to pass to prop.test

## Value

Object of class "pairwise.htest"

## See Also

[prop.test](#), [p.adjust](#)

## Examples

```
smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
pairwise.prop.test(smokers, patients)
```

---

|                 |                         |
|-----------------|-------------------------|
| pairwise.t.test | <i>Pairwise t tests</i> |
|-----------------|-------------------------|

---

## Description

Calculate pairwise comparisons between group levels with corrections for multiple testing

## Usage

```
pairwise.t.test(x, g, p.adjust.method = p.adjust.methods,
 pool.sd = !paired, paired = FALSE,
 alternative = c("two.sided", "less", "greater"),
 ...)
```

## Arguments

|                              |                                                                                                                      |
|------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>x</code>               | response vector.                                                                                                     |
| <code>g</code>               | grouping vector or factor.                                                                                           |
| <code>p.adjust.method</code> | Method for adjusting p values (see <a href="#">p.adjust</a> ).                                                       |
| <code>pool.sd</code>         | switch to allow/disallow the use of a pooled SD                                                                      |
| <code>paired</code>          | a logical indicating whether you want paired t-tests.                                                                |
| <code>alternative</code>     | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". |
| <code>...</code>             | additional arguments to pass to <code>t.test</code> .                                                                |

## Details

The `pool.sd` switch calculates a common SD for all groups and uses that for all comparisons (this can be useful if some groups are small). This method does not actually call `t.test`, so extra arguments are ignored. Pooling does not generalize to paired tests so `pool.sd` and `paired` cannot both be TRUE.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting `alternative` to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

## Value

Object of class "pairwise.htest"

## See Also

[t.test](#), [p.adjust](#)

## Examples

```
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adj = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()
```

**pairwise.table**      *Tabulate p values for pairwise comparisons*

### Description

Creates table of p values for pairwise comparisons with corrections for multiple testing.

### Usage

```
pairwise.table(compare.levels, level.names, p.adjust.method)
```

### Arguments

|                              |                                                         |
|------------------------------|---------------------------------------------------------|
| <code>compare.levels</code>  | Function to compute (raw) p value given indices i and j |
| <code>level.names</code>     | Names of the group levels                               |
| <code>p.adjust.method</code> | Method for multiple testing adjustment                  |

### Details

Functions that do multiple group comparisons create separate `compare.levels` functions (assumed to be symmetrical in i and j) and passes them to this function.

### Value

Table of p values in lower triangular form.

### See Also

[pairwise.t.test](#), et al.

**pairwise.wilcox.test**      *Pairwise Wilcoxon Rank Sum Tests*

### Description

Calculate pairwise comparisons between group levels with corrections for multiple testing.

### Usage

```
pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods,
 paired = FALSE, ...)
```

### Arguments

|                              |                                                                |
|------------------------------|----------------------------------------------------------------|
| <code>x</code>               | response vector.                                               |
| <code>g</code>               | grouping vector or factor.                                     |
| <code>p.adjust.method</code> | method for adjusting p values (see <a href="#">p.adjust</a> ). |
| <code>paired</code>          | a logical indicating whether you want a paired test.           |
| <code>...</code>             | additional arguments to pass to <a href="#">wilcox.test</a> .  |

## Details

Extra arguments that are passed on to `wilcox.test` may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting `alternative` to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

## Value

Object of class "pairwise.htest"

## See Also

[wilcox.test](#), [p.adjust](#)

## Examples

```
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
These give warnings because of ties :
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adj = "bonf")
detach()
```

plot.acf

*Plot Autocovariance and Autocorrelation Functions*

## Description

Plot method for objects of class "acf".

## Usage

```
S3 method for class acf
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL,
 ylim = NULL, main = NULL,
 ci.col = "blue", ci.type = c("white", "ma"),
 max.mfrow = 6, ask = Npgs > 1 && dev.interactive(),
 mar = if(nser > 2) c(3,2,2,0.8) else par("mar"),
 oma = if(nser > 2) c(1,1.2,1,1) else par("oma"),
 mgp = if(nser > 2) c(1.5,0.6,0) else par("mgp"),
 xpd = par("xpd"),
 cex.main = if(nser > 2) 1 else par("cex.main"),
 verbose = getOption("verbose"),
 ...)
```

## Arguments

- |                   |                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | an object of class "acf".                                                                                                               |
| <code>ci</code>   | coverage probability for confidence interval. Plotting of the confidence interval is suppressed if <code>ci</code> is zero or negative. |
| <code>type</code> | the type of plot to be drawn, default to histogram like vertical lines.                                                                 |

|                                           |                                                                                                                                                          |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>xlab</code>                         | the x label of the plot.                                                                                                                                 |
| <code>ylab</code>                         | the y label of the plot.                                                                                                                                 |
| <code>ylim</code>                         | numeric of length 2 giving the y limits for the plot.                                                                                                    |
| <code>main</code>                         | overall title for the plot.                                                                                                                              |
| <code>ci.col</code>                       | colour to plot the confidence interval lines.                                                                                                            |
| <code>ci.type</code>                      | should the confidence limits assume a white noise input or for lag $k$ an $MA(k-1)$ input?                                                               |
| <code>max.mfrow</code>                    | positive integer; for multivariate $x$ indicating how many rows and columns of plots should be put on one page, using <code>par(mfrow = c(m,m))</code> . |
| <code>ask</code>                          | logical; if TRUE, the user is asked before a new page is started.                                                                                        |
| <code>mar, oma, mgp, xpd, cex.main</code> | graphics parameters as in <code>par(*)</code> , by default adjusted to use smaller than default margins for multivariate $x$ only.                       |
| <code>verbose</code>                      | logical. Should R report extra information on progress?                                                                                                  |
| <code>...</code>                          | graphics parameters to be passed to the plotting routines.                                                                                               |

**Note**

The confidence interval plotted in `plot.acf` is based on an *uncorrelated* series and should be treated with appropriate caution. Using `ci.type = "ma"` may be less potentially misleading.

**See Also**

`acf` which calls `plot.acf` by default.

**Examples**

```
require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start = c(1961, 1), frequency = 12)
z7 <- ts(matrix(rnorm(700), 100, 7), start = c(1961, 1), frequency = 12)
acf(z4)
acf(z7, max.mfrow = 7) # squeeze onto 1 page
acf(z7) # multi-page
```

**Description**

The plot method for density objects.

**Usage**

```
S3 method for class density
plot(x, main = NULL, xlab = NULL, ylab = "Density", type = "l",
 zero.line = TRUE, ...)
```

**Arguments**

```

x a "density" object.
main, xlab, ylab, type
 plotting parameters with useful defaults.
...
 further plotting parameters.
zero.line logical; if TRUE, add a base line at $y = 0$

```

**Value**

None.

**See Also**

[density](#).

|                               |                                              |
|-------------------------------|----------------------------------------------|
| <code>plot.HoltWinters</code> | <i>Plot function for HoltWinters objects</i> |
|-------------------------------|----------------------------------------------|

**Description**

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

**Usage**

```
S3 method for class HoltWinters
plot(x, predicted.values = NA, intervals = TRUE,
 separator = TRUE, col = 1, col.predicted = 2,
 col.intervals = 4, col.separator = 1, lty = 1,
 lty.predicted = 1, lty.intervals = 1, lty.separator = 3,
 ylab = "Observed / Fitted",
 main = "Holt-Winters filtering",
 ylim = NULL, ...)
```

**Arguments**

|                                           |                                                                                      |
|-------------------------------------------|--------------------------------------------------------------------------------------|
| <code>x</code>                            | Object of class "HoltWinters"                                                        |
| <code>predicted.values</code>             | Predicted values as returned by <code>predict.HoltWinters</code>                     |
| <code>intervals</code>                    | If TRUE, the prediction intervals are plotted (default).                             |
| <code>separator</code>                    | If TRUE, a separating line between fitted and predicted values is plotted (default). |
| <code>col, lty</code>                     | Color/line type of original data (default: black solid).                             |
| <code>col.predicted, lty.predicted</code> | Color/line type of fitted and predicted values (default: red solid).                 |
| <code>col.intervals, lty.intervals</code> | Color/line type of prediction intervals (default: blue solid).                       |
| <code>col.separator, lty.separator</code> | Color/line type of observed/predicted values separator (default: black dashed).      |

|                   |                                                                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ylab</code> | Label of the y-axis.                                                                                                                                                  |
| <code>main</code> | Main title.                                                                                                                                                           |
| <code>ylim</code> | Limits of the y-axis. If <code>NULL</code> , the range is chosen such that the plot contains the original series, the fitted values, and the predicted values if any. |
| <code>...</code>  | Other graphics parameters.                                                                                                                                            |

**plot.isoreg**

*Plot Method for isoreg Objects*

**Description**

The `plot` and `lines` method for R objects of class `isoreg`.

**Usage**

```
S3 method for class isoreg
plot(x, plot.type = c("single", "row.wise", "col.wise"),
 main = paste("Isotonic regression", deparse(x$call)),
 main2 = "Cumulative Data and Convex Minorant",
 xlab = "x0", ylab = "x$y",
 par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
 mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
 mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
 grid = length(x$x) < 12, ...)

S3 method for class isoreg
lines(x, col = "red", lwd = 1.5,
 do.points = FALSE, cex = 1.5, pch = 13, ...)
```

### Arguments

|                                 |                                                                                                                                                                                               |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                  | an <a href="#">isoreg</a> object.                                                                                                                                                             |
| <code>plot.type</code>          | character indicating which type of plot is desired. The first (default) only draws the data and the fit, where the others add a plot of the cumulative data and fit.                          |
| <code>main</code>               | main title of plot, see <a href="#">title</a> .                                                                                                                                               |
| <code>main2</code>              | title for second (cumulative) plot.                                                                                                                                                           |
| <code>xlab, ylab</code>         | x- and y- axis annotation.                                                                                                                                                                    |
| <code>par.fit</code>            | a <a href="#">list</a> of arguments (for <a href="#">points</a> and <a href="#">lines</a> ) for drawing the fit.                                                                              |
| <code>mar, mgp</code>           | graphical parameters, see <a href="#">par</a> , mainly for the case of two plots.                                                                                                             |
| <code>grid</code>               | logical indicating if grid lines should be drawn. If true, <a href="#">grid()</a> is used for the first plot, where as vertical lines are drawn at ‘touching’ points for the cumulative plot. |
| <code>do.points</code>          | for <a href="#">lines()</a> : logical indicating if the step points should be drawn as well (and as they are drawn in <a href="#">plot()</a> ).                                               |
| <code>col, lwd, cex, pch</code> | graphical arguments for <a href="#">lines()</a> , where <code>cex</code> and <code>pch</code> are only used when <code>do.points</code> is TRUE.                                              |
| <code>...</code>                | further arguments passed to and from methods.                                                                                                                                                 |

[isoreg](#) for computation of [isoreg](#) objects.

### Examples

```
require(graphics)

utils::example(isoreg) # for the examples there

plot(y3, main = "simple plot(.) + lines(<isoreg>)")
lines(ir3)

same plot as above, "proving" that only ranks of x are important
plot(isoreg(2^(1:9), c(1,0,4,3,3,5,4,2,0)), plot.type = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.t="r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

experiment a bit with these (C-c C-j):
plot(isoreg(sample(9), y3), plot.type = "row")
plot(isoreg(sample(9), y3), plot.type = "col.wise")

plot(ir <- isoreg(sample(10), sample(10, replace = TRUE)),
 plot.type = "r")
```

---

**plot.lm***Plot Diagnostics for an lm Object*

---

## Description

Six plots (selectable by `which`) are currently available: a plot of residuals against fitted values, a Scale-Location plot of  $\sqrt{|residuals|}$  against fitted values, a Normal Q-Q plot, a plot of Cook's distances versus row labels, a plot of residuals against leverages, and a plot of Cook's distances against leverage/(1-leverage). By default, the first three and 5 are provided.

## Usage

```
S3 method for class lm
plot(x, which = c(1:3, 5),
 caption = list("Residuals vs Fitted", "Normal Q-Q",
 "Scale-Location", "Cooks distance",
 "Residuals vs Leverage",
 expression("Cooks dist vs Leverage " * h[ii] / (1 - h[ii]))),
 panel = if(add.smooth) panel.smooth else points,
 sub.caption = NULL, main = "",
 ask = prod(par("mfcol")) < length(which) && dev.interactive(),
 ...,
 id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
 qqline = TRUE, cook.levels = c(0.5, 1.0),
 add.smooth = getOption("add.smooth"), label.pos = c(4,2),
 cex.caption = 1)
```

## Arguments

|                          |                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | <code>lm</code> object, typically result of <code>lm</code> or <code>glm</code> .                                                                                                                                       |
| <code>which</code>       | if a subset of the plots is required, specify a subset of the numbers 1:6.                                                                                                                                              |
| <code>caption</code>     | captions to appear above the plots; <code>character</code> vector or <code>list</code> of valid graphics annotations, see <code>as.graphicsAnnot</code> . Can be set to "" or NA to suppress all captions.              |
| <code>panel</code>       | panel function. The useful alternative to <code>points</code> , <code>panel.smooth</code> can be chosen by <code>add.smooth = TRUE</code> .                                                                             |
| <code>sub.caption</code> | common title—above the figures if there are more than one; used as <code>sub(s\$title)</code> otherwise. If <code>NULL</code> , as by default, a possible abbreviated version of <code>deparse(x\$call)</code> is used. |
| <code>main</code>        | title to each plot—in addition to <code>caption</code> .                                                                                                                                                                |
| <code>ask</code>         | logical; if <code>TRUE</code> , the user is <i>asked</i> before each plot, see <code>par(ask=.)</code> .                                                                                                                |
| <code>...</code>         | other parameters to be passed through to plotting functions.                                                                                                                                                            |
| <code>id.n</code>        | number of points to be labelled in each plot, starting with the most extreme.                                                                                                                                           |
| <code>labels.id</code>   | vector of labels, from which the labels for extreme points will be chosen. <code>NULL</code> uses observation numbers.                                                                                                  |
| <code>cex.id</code>      | magnification of point labels.                                                                                                                                                                                          |
| <code>qqline</code>      | logical indicating if a <code>qqline()</code> should be added to the normal Q-Q plot.                                                                                                                                   |

|             |                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------|
| cook.levels | levels of Cook's distance at which to draw contours.                                              |
| add.smooth  | logical indicating if a smoother should be added to most plots; see also panel above.             |
| label.pos   | positioning of labels, for the left half and right half of the graph respectively, for plots 1-3. |
| cex.caption | controls the size of caption.                                                                     |

## Details

sub.caption—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot, also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness ( $\sqrt{|E|}$ ) is much less skewed than  $|E|$  for Gaussian zero-mean  $E$ ).

The ‘S-L’, the Q-Q, and the Residual-Leverage plot, use *standardized* residuals which have identical variance (under the hypothesis). They are given as  $R_i/(s \times \sqrt{1 - h_{ii}})$  where  $h_{ii}$  are the diagonal entries of the hat matrix, [influence\(\)\\$hat](#) (see also [hat](#)), and where the Residual-Leverage plot uses standardized Pearson residuals ([residuals.glm\(type = "pearson"\)](#)) for  $R[i]$ .

The Residual-Leverage plot shows contours of equal Cook's distance, for values of cook.levels (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced [aov](#) situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook's distance vs leverage/(1-leverage) plot, contours of standardized residuals that are equal in magnitude are lines through the origin. The contour lines are labelled with the magnitudes.

## Examples

```

require(graphics)

Analysis of the life-cycle savings data
given in Belsley, Kuh and Welsch.
lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)
plot(lm.SR)

4 plots on 1 page;
allow room for printing model formula in outer margin:
par(mfrow = c(2, 2), oma = c(0, 0, 2, 0))
plot(lm.SR)
plot(lm.SR, id.n = NULL) # no ids
plot(lm.SR, id.n = 5, labels.id = NULL) # 5 id numbers

Was default in R <= 2.1.x:
Cooks distances instead of Residual-Leverage plot
plot(lm.SR, which = 1:4)

Fit a smooth curve, where applicable:
plot(lm.SR, panel = panel.smooth)
Gives a smoother curve
plot(lm.SR, panel = function(x, y) panel.smooth(x, y, span = 1))

par(mfrow = c(2,1)) # same oma as above
plot(lm.SR, which = 1:2, sub.caption = "Saving Rates, n=50, p=5")

```

## plot.ppr

## *Plot Ridge Functions for Projection Pursuit Regression Fit*

### Description

Plot ridge functions for projection pursuit regression fit.

### Usage

```

S3 method for class ppr
plot(x, ask, type = "o", ...)

```

### Arguments

- |      |                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------|
| x    | A fit of class "ppr" as produced by a call to ppr.                                                               |
| ask  | the graphics parameter ask: see par for details. If set to TRUE will ask between the plot of each cross-section. |
| type | the type of line to draw                                                                                         |
| ...  | further graphical parameters                                                                                     |

### Value

None

### Side Effects

A series of plots are drawn on the current graphical device, one for each term in the fit.

### See Also

[ppr](#), [par](#)

### Examples

```
require(graphics)

with(rock, {
 area1 <- area/10000; peri1 <- peri/10000
 par(mfrow = c(3,2)) # maybe: , pty = "s")
 rock.ppr <- ppr(log(perm) ~ area1 + peri1 + shape,
 data = rock, nterms = 2, max.terms = 5)
 plot(rock.ppr, main = "ppr(log(perm)~ ., nterms=2, max.terms=5)")
 plot(update(rock.ppr, bass = 5), main = "update(..., bass = 5)")
 plot(update(rock.ppr, sm.method = "gcv", gcvpen = 2),
 main = "update(..., sm.method=\"gcv\", gcvpen=2)")
})
```

**plot.profile.nls**      *Plot a profile.nls Object*

### Description

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with [nls](#) and profiled with [profile.nls](#).

### Usage

```
S3 method for class profile.nls
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100,
 absVal = TRUE, ylab = NULL, lty = 2, ...)
```

### Arguments

|                        |                                                                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object of class "profile.nls"                                                                                                                                                    |
| <code>levels</code>    | levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually <code>conf</code> is used instead of giving <code>levels</code> explicitly. |
| <code>conf</code>      | a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to <code>c(0.99, 0.95, 0.90, 0.80, 0.50)</code> .                          |
| <code>absVal</code>    | a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to <code>TRUE</code> .                                  |
| <code>lty</code>       | the line type to be used for axis and dropped lines.                                                                                                                                |
| <code>ylab, ...</code> | other arguments to the <a href="#">plot.default</a> function can be passed here (but not <code>xlab</code> , <code>xlim</code> , <code>ylim</code> nor <code>type</code> ).         |

## Details

The plots are produced in a set of hard-coded colours, but as these are coded by number their effect can be changed by setting the [palette](#). Colour 1 is used for the axes and 4 for the profile itself. Colours 3 and 6 are used for the axis line at zero and the horizontal/vertical lines dropping to the axes.

## Examples

```
require(graphics)

obtain the fitted object
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
get the profile for the fitted model
pr1 <- profile(fm1, alpha = 0.05)
opar <- par(mfrow = c(2,2), oma = c(1.1, 0, 1.1, 0), las = 1)
plot(pr1, conf = c(95, 90, 80, 50)/100)
plot(pr1, conf = c(95, 90, 80, 50)/100, absVal = FALSE)
mtext("Confidence intervals based on the profile sum of squares",
 side = 3, outer = TRUE)
mtext("BOD data - confidence levels of 50%, 80%, 90% and 95%",
 side = 1, outer = TRUE)
par(opar)
```

## Description

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.

## Usage

```
S3 method for class spec
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
 xlab = "frequency", ylab = NULL, type = "l",
 ci.col = "blue", ci.lty = 3,
 main = NULL, sub = NULL,
 plot.type = c("marginal", "coherency", "phase"),
```

```

 ...)

plot.spec.phase(x, ci = 0.95,
 xlab = "frequency", ylab = "phase",
 ylim = c(-pi, pi), type = "l",
 main = NULL, ci.col = "blue", ci.lty = 3, ...)

plot.spec.coherency(x, ci = 0.95,
 xlab = "frequency",
 ylab = "squared coherency",
 ylim = c(0, 1), type = "l",
 main = NULL, ci.col = "blue", ci.lty = 3, ...)

```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object of class "spec".                                                                                                                                                                                                                                                                           |
| <code>add</code>       | logical. If TRUE, add to already existing plot. Only valid for <code>plot.type = "marginal"</code> .                                                                                                                                                                                                 |
| <code>ci</code>        | coverage probability for confidence interval. Plotting of the confidence bar/limits is omitted unless <code>ci</code> is strictly positive.                                                                                                                                                          |
| <code>log</code>       | If "dB", plot on log10 (decibel) scale (as S-PLUS), otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless <code>options(ts.S.compat = TRUE)</code> has been set, when it is "dB". Only valid for <code>plot.type = "marginal"</code> . |
| <code>xlab</code>      | the x label of the plot.                                                                                                                                                                                                                                                                             |
| <code>ylab</code>      | the y label of the plot. If missing a suitable label will be constructed.                                                                                                                                                                                                                            |
| <code>type</code>      | the type of plot to be drawn, defaults to lines.                                                                                                                                                                                                                                                     |
| <code>ci.col</code>    | colour for plotting confidence bar or confidence intervals for coherency and phase.                                                                                                                                                                                                                  |
| <code>ci.lty</code>    | line type for confidence intervals for coherency and phase.                                                                                                                                                                                                                                          |
| <code>main</code>      | overall title for the plot. If missing, a suitable title is constructed.                                                                                                                                                                                                                             |
| <code>sub</code>       | a sub title for the plot. Only used for <code>plot.type = "marginal"</code> . If missing, a description of the smoothing is used.                                                                                                                                                                    |
| <code>plot.type</code> | For multivariate time series, the type of plot required. Only the first character is needed.                                                                                                                                                                                                         |
| <code>ylim, ...</code> | Graphical parameters.                                                                                                                                                                                                                                                                                |

[spectrum](#)

---

**plot.stepfun***Plot Step Functions*

---

**Description**

Method of the generic [plot](#) for [stepfun](#) objects and utility for plotting piecewise constant functions.

**Usage**

```
S3 method for class "stepfun"
plot(x, xval, xlim = range(c(y, Fn.kn)),
 xlab = "x", ylab = "f(x)", main = NULL,
 add = FALSE, verticals = TRUE, do.points = (n < 1000),
 pch = par("pch"), col = par("col"),
 col.points = col, cex.points = par("cex"),
 col.hor = col, col.vert = col,
 lty = par("lty"), lwd = par("lwd"), ...)

S3 method for class "stepfun"
lines(x, ...)
```

**Arguments**

|                         |                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an R object inheriting from "stepfun".                                                                                                                         |
| <code>xval</code>       | numeric vector of abscissa values at which to evaluate <code>x</code> . Defaults to <a href="#">knots</a> ( <code>x</code> ) restricted to <code>xlim</code> . |
| <code>xlim, ylim</code> | limits for the plot region: see <a href="#">plot.window</a> . Both have sensible defaults if omitted.                                                          |
| <code>xlab, ylab</code> | labels for x and y axis.                                                                                                                                       |
| <code>main</code>       | main title.                                                                                                                                                    |
| <code>add</code>        | logical; if TRUE only <i>add</i> to an existing plot.                                                                                                          |
| <code>verticals</code>  | logical; if TRUE, draw vertical lines at steps.                                                                                                                |
| <code>do.points</code>  | logical; if TRUE, also draw points at the ( <code>xlim</code> restricted) knot locations. Default is true, for sample size < 1000.                             |
| <code>pch</code>        | character; point character if <code>do.points</code> .                                                                                                         |
| <code>col</code>        | default color of all points and lines.                                                                                                                         |
| <code>col.points</code> | character or integer code; color of points if <code>do.points</code> .                                                                                         |
| <code>cex.points</code> | numeric; character expansion factor if <code>do.points</code> .                                                                                                |
| <code>col.hor</code>    | color of horizontal lines.                                                                                                                                     |
| <code>col.vert</code>   | color of vertical lines.                                                                                                                                       |
| <code>lty, lwd</code>   | line type and thickness for all lines.                                                                                                                         |
| <code>...</code>        | further arguments of <a href="#">plot</a> (.), or if( <code>add</code> ) <a href="#">segments</a> (.).                                                         |

**Value**

A list with two components

- t abscissa (x) values, including the two outermost ones.
- y y values ‘in between’ the t[].

**Author(s)**

Martin Maechler <maechler@stat.math.ethz.ch>, 1990, 1993; ported to R, 1997.

**See Also**

[ecdf](#) for empirical distribution functions as special step functions, [approxfun](#) and [splinefun](#).

**Examples**

```
require(graphics)

y0 <- c(1,2,4,3)
sfu0 <- stepfun(1:3, y0, f = 0)
sfu.2 <- stepfun(1:3, y0, f = .2)
sfu1 <- stepfun(1:3, y0, right = TRUE)

tt <- seq(0, 3, by = 0.1)
op <- par(mfrow = c(2,2))
plot(sfu0); plot(sfu0, xval = tt, add = TRUE, col.hor = "bisque")
plot(sfu.2); plot(sfu.2, xval = tt, add = TRUE, col = "orange") # all colors
plot(sfu1); lines(sfu1, xval = tt, col.hor = "coral")
##-- This is revealing :
plot(sfu0, verticals = FALSE,
 main = "stepfun(x, y0, f=f) for f = 0, .2, 1")
for(i in 1:3)
 lines(list(sfu0, sfu.2, stepfun(1:3, y0, f = 1))[[i]], col = i)
legend(2.5, 1.9, paste("f =", c(0, 0.2, 1)), col = 1:3, lty = 1, y.intersp = 1)
par(op)

Extend and/or restrict viewport:
plot(sfu0, xlim = c(0,5), ylim = c(0, 3.5),
 main = "plot(stepfun(*), xlim= . , ylim = .)")

##-- this works too (automatic call to ecdf(.)):
plot.stepfun(rt(50, df = 3), col.vert = "gray20")
```

**Description**

Plotting method for objects inheriting from class "ts".

## Usage

```
S3 method for class ts
plot(x, y = NULL, plot.type = c("multiple", "single"),
 xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
 mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
 oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

S3 method for class ts
lines(x, ...)
```

## Arguments

|                                   |                                                                                                                                                                                                           |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                 | time series objects, usually inheriting from class "ts".                                                                                                                                                  |
| <code>plot.type</code>            | for multivariate time series, should the series by plotted separately (with a common time axis) or on a single plot?                                                                                      |
| <code>xy.labels</code>            | logical, indicating if <code>text()</code> labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.  |
| <code>xy.lines</code>             | logical, indicating if <code>lines</code> should be drawn for an x-y plot. Defaults to the value of <code>xy.labels</code> if that is logical, otherwise to TRUE.                                         |
| <code>panel</code>                | a function( <code>x, col, bg, pch, type, ...</code> ) which gives the action to be carried out in each panel of the display for <code>plot.type = "multiple"</code> . The default is <code>lines</code> . |
| <code>nc</code>                   | the number of columns to use when <code>type = "multiple"</code> . Defaults to 1 for up to 4 series, otherwise to 2.                                                                                      |
| <code>yax.flip</code>             | logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when <code>type = "multiple"</code> .                                            |
| <code>mar.multi, oma.multi</code> | the (default) <code>par</code> settings for <code>plot.type = "multiple"</code> . Modify with care!                                                                                                       |
| <code>axes</code>                 | logical indicating if x- and y- axes should be drawn.                                                                                                                                                     |
| <code>...</code>                  | additional graphical arguments, see <code>plot, plot.default</code> and <code>par</code> .                                                                                                                |

## Details

If `y` is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on `plot.type`.

If `y` is present, both `x` and `y` must be univariate, and a scatter plot  $y \sim x$  will be drawn, enhanced by using `text` if `xy.labels` is TRUE or character, and `lines` if `xy.lines` is TRUE.

## See Also

`ts` for basic time series construction and access functionality.

## Examples

```
require(graphics)

Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8),
 start = c(1961, 1), frequency = 12)
```

```

plot(z, yax.flip = TRUE)
plot(z, axes = FALSE, ann = FALSE, frame.plot = TRUE,
 mar.multi = c(0,0,0,0), oma.multi = c(1,1,5,1))
title("plot(ts(..), axes=FALSE, ann=FALSE, frame.plot=TRUE, mar..., oma...")

z <- window(z[,1:3], end = c(1969,12))
plot(z, type = "b") # multiple
plot(z, plot.type = "single", lty = 1:3, col = 4:2)

A phase plot:
plot(nhtemp, c(nhtemp[-1], NA), cex = .8, col = "blue",
 main = "Lag plot of New Haven temperatures")
a clearer way to do this would be
Not run:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
 main = "Lag plot of New Haven temperatures")

End(Not run)

xy.lines and xy.labels are FALSE for large series:
plot(lag(sunspots, 1), sunspots, pch = ".")

SMI <- EuStockMarkets[, "SMI"]
plot(lag(SMI, 1), SMI, pch = ".")
plot(lag(SMI, 20), SMI, pch = ".", log = "xy",
 main = "4 weeks lagged SMI stocks -- log scale", xy.lines = TRUE)

```

## Description

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter `lambda`.

## Usage

```
dpois(x, lambda, log = FALSE)
ppois(q, lambda, lower.tail = TRUE, log.p = FALSE)
qpois(p, lambda, lower.tail = TRUE, log.p = FALSE)
rpois(n, lambda)
```

## Arguments

|                         |                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------|
| <code>x</code>          | vector of (non-negative integer) quantiles.                                           |
| <code>q</code>          | vector of quantiles.                                                                  |
| <code>p</code>          | vector of probabilities.                                                              |
| <code>n</code>          | number of random values to return.                                                    |
| <code>lambda</code>     | vector of (non-negative) means.                                                       |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .               |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ . |

## Details

The Poisson distribution has density

$$p(x) = \frac{\lambda^x e^{-\lambda}}{x!}$$

for  $x = 0, 1, 2, \dots$ . The mean and variance are  $E(X) = \text{Var}(X) = \lambda$ .

If an element of  $x$  is not integer, the result of `dpois` is zero, with a warning.  $p(x)$  is computed using Loader's algorithm, see the reference in [dbinom](#).

The quantile is right continuous: `qpois(p, lambda)` is the smallest integer  $x$  such that  $P(X \leq x) \geq p$ .

Setting `lower.tail = FALSE` allows to get much more precise results when the default, `lower.tail = TRUE` would return 1, see the example below.

## Value

`dpois` gives the (log) density, `ppois` gives the (log) distribution function, `qpois` gives the quantile function, and `rpois` generates random deviates.

Invalid `lambda` will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rpois`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

## Source

`dpois` uses C code contributed by Catherine Loader (see [dbinom](#)).

`ppois` uses `pgamma`.

`qpois` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

`rpois` uses

Ahrens, J. H. and Dieter, U. (1982). Computer generation of Poisson deviates from modified normal distributions. *ACM Transactions on Mathematical Software*, **8**, 163–179.

[poisson.test](#).

## Examples

```
require(graphics)

-log(dpois(0:7, lambda = 1) * gamma(1+ 0:7)) # == 1
Ni <- rpois(50, lambda = 4); table(factor(Ni, 0:max(Ni)))

1 - ppois(10*(15:25), lambda = 100) # becomes 0 (cancellation)
ppois(10*(15:25), lambda = 100, lower.tail = FALSE) # no cancellation
```

```

par(mfrow = c(2, 1))
x <- seq(-0.01, 5, 0.01)
plot(x, ppois(x, 1), type = "s", ylab = "F(x)", main = "Poisson(1) CDF")
plot(x, pbinom(x, 100, 0.01), type = "s", ylab = "F(x)",
 main = "Binomial(100, 0.01) CDF")

```

**poisson.test***Exact Poisson tests***Description**

Performs an exact test of a simple null hypothesis about the rate parameter in Poisson distribution, or for the ratio between two rate parameters.

**Usage**

```
poisson.test(x, T = 1, r = 1,
 alternative = c("two.sided", "less", "greater"),
 conf.level = 0.95)
```

**Arguments**

|                          |                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | number of events. A vector of length one or two.                                                                                   |
| <code>T</code>           | time base for event count. A vector of length one or two.                                                                          |
| <code>r</code>           | hypothesized rate or rate ratio                                                                                                    |
| <code>alternative</code> | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. |
| <code>conf.level</code>  | confidence level for the returned confidence interval.                                                                             |

**Details**

Confidence intervals are computed similarly to those of [binom.test](#) in the one-sample case, and using [binom.test](#) in the two sample case.

**Value**

A list with class "htest" containing the following components:

|                          |                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the number of events (in the first sample if there are two.)                               |
| <code>parameter</code>   | the corresponding expected count                                                           |
| <code>p.value</code>     | the p-value of the test.                                                                   |
| <code>conf.int</code>    | a confidence interval for the rate or rate ratio.                                          |
| <code>estimate</code>    | the estimated rate or rate ratio.                                                          |
| <code>null.value</code>  | the rate or rate ratio under the null, <code>r</code> .                                    |
| <code>alternative</code> | a character string describing the alternative hypothesis.                                  |
| <code>method</code>      | the character string "Exact Poisson test" or "Comparison of Poisson rates" as appropriate. |
| <code>data.name</code>   | a character string giving the names of the data.                                           |

**Note**

The rate parameter in Poisson data is often given based on a “time on test” or similar quantity (person-years, population size, or expected number of cases from mortality tables). This is the role of the *T* argument.

The one-sample case is effectively the binomial test with a very large *n*. The two sample case is converted to a binomial test by conditioning on the total event count, and the rate ratio is directly related to the odds in that binomial distribution.

**See Also**

poisson.test(c(11, 6+8+7), c(800, 1083+1050+878))
```

**poly**

*Compute Orthogonal Polynomials*

**Description**

Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points *x*. These are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.

**Usage**

```
poly(x, ..., degree = 1, coefs = NULL, raw = FALSE)
polym(..., degree = 1, raw = FALSE)

S3 method for class poly
predict(object, newdata, ...)
```

**Arguments**

|                           |                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i> , <i>newdata</i> | a numeric vector at which to evaluate the polynomial. <i>x</i> can also be a matrix. Missing values are not allowed in <i>x</i> . |
| <i>degree</i>             | the degree of the polynomial. Must be less than the number of unique points if <i>raw</i> = TRUE.                                 |
| <i>coefs</i>              | for prediction, coefficients from a previous fit.                                                                                 |
| <i>raw</i>                | if true, use raw and not orthogonal polynomials.                                                                                  |
| <i>object</i>             | an object inheriting from class "poly", normally the result of a call to poly with a single vector argument.                      |
| ...                       | <i>poly</i> , <i>polym</i> : further vectors.<br><i>predict.poly</i> : arguments to be passed to or from other methods.           |

## Details

Although formally degree should be named (as it follows . . .), an unnamed second argument of length 1 will be interpreted as the degree.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the predict part of the code.

## Value

For poly with a single vector argument:

A matrix with rows corresponding to points in x and columns corresponding to the degree, with attributes "degree" specifying the degrees of the columns and (unless raw = TRUE) "coefs" which contains the centering and normalization constants used in constructing the orthogonal polynomials. The matrix has given class c("poly", "matrix").

Other cases of poly and polym, and predict.poly: a matrix.

## Note

This routine is intended for statistical purposes such as contr.poly: it does not attempt to orthogonalize to machine accuracy.

## See Also

[contr.poly](#).

[cars](#) for an example of polynomial regression.

## Examples

```
od <- options(digits = 3) # avoid too much visual clutter
(z <- poly(1:10, 3))
predict(z, seq(2, 4, 0.5))
zapsmall(poly(seq(4, 6, 0.5), 3, coefs = attr(z, "coefs")))

zapsmall(polym(1:4, c(1, 4:6), degree = 3)) # or just poly()
zapsmall(poly(cbind(1:4, c(1, 4:6)), degree = 3))
options(od)
```

## Description

Creates a link object based on the link function  $\eta = \mu^\lambda$ .

**Usage**

```
power(lambda = 1)
```

**Arguments**

lambda            a real number.

**Details**

If lambda is non-positive, it is taken as zero, and the log link is obtained. The default lambda = 1 gives the identity link.

**Value**

A list with components linkfun, linkinv, mu.eta, and valideta. See [make.link](#) for information on their meaning.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

[make.link](#), [family](#)

To raise a number to a power, see [Arithmetic](#).

To calculate the power of a test, see various functions in the **stats** package, e.g., [power.t.test](#).

**Examples**

```
power()
quasi(link = power(1/3))[c("linkfun", "linkinv")]
```

**power.anova.test**      *Power Calculations for Balanced One-Way Analysis of Variance Tests*

**Description**

Compute power of test or determine parameters to obtain target power.

**Usage**

```
power.anova.test(groups = NULL, n = NULL,
 between.var = NULL, within.var = NULL,
 sig.level = 0.05, power = NULL)
```

### Arguments

|             |                                                   |
|-------------|---------------------------------------------------|
| groups      | Number of groups                                  |
| n           | Number of observations (per group)                |
| between.var | Between group variance                            |
| within.var  | Within group variance                             |
| sig.level   | Significance level (Type I error probability)     |
| power       | Power of test (1 minus Type II error probability) |

### Details

Exactly one of the parameters `groups`, `n`, `between.var`, `power`, `within.var`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has non-`NULL` default so `NULL` must be explicitly passed if you want it computed.

### Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with `method` and `note` elements.

### Note

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

### Author(s)

Claus Ekstrøm

### See Also

[anova](#), [lm](#), [uniroot](#)

### Examples

```
power.anova.test(groups = 4, n = 5, between.var = 1, within.var = 3)
Power = 0.3535594

power.anova.test(groups = 4, between.var = 1, within.var = 3,
 power = .80)
n = 11.92613

Assume we have prior knowledge of the group means:
groupmeans <- c(120, 130, 140, 150)
power.anova.test(groups = length(groupmeans),
 between.var = var(groupmeans),
 within.var = 500, power = .90) # n = 15.18834
```

---

**power.prop.test***Power Calculations for Two-Sample Test for Proportions*

---

**Description**

Compute power of test, or determine parameters to obtain target power.

**Usage**

```
power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05,
 power = NULL,
 alternative = c("two.sided", "one.sided"),
 strict = FALSE)
```

**Arguments**

|             |                                                   |
|-------------|---------------------------------------------------|
| n           | Number of observations (per group)                |
| p1          | probability in one group                          |
| p2          | probability in other group                        |
| sig.level   | Significance level (Type I error probability)     |
| power       | Power of test (1 minus Type II error probability) |
| alternative | One- or two-sided test                            |
| strict      | Use strict interpretation in two-sided case       |

**Details**

Exactly one of the parameters n, p1, p2, power, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that sig.level has a non-NULL default so NULL must be explicitly passed if you want it computed.

If strict = TRUE is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

**Value**

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

**Note**

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of them is computed p1 < p2 will hold, although this is not enforced when both are specified.

**Author(s)**

Peter Dalgaard. Based on previous work by Claus Ekstrøm

**See Also**

**Examples**

```
power.prop.test(n = 50, p1 = .50, p2 = .75)
power.prop.test(p1 = .50, p2 = .75, power = .90)
power.prop.test(n = 50, p1 = .5, power = .90)
```

---

power.t.test

*Power calculations for one and two sample t tests*

---

**Description**

Compute power of test, or determine parameters to obtain target power.

**Usage**

```
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05,
 power = NULL,
 type = c("two.sample", "one.sample", "paired"),
 alternative = c("two.sided", "one.sided"),
 strict = FALSE)
```

**Arguments**

|             |                                                   |
|-------------|---------------------------------------------------|
| n           | Number of observations (per group)                |
| delta       | True difference in means                          |
| sd          | Standard deviation                                |
| sig.level   | Significance level (Type I error probability)     |
| power       | Power of test (1 minus Type II error probability) |
| type        | Type of t test                                    |
| alternative | One- or two-sided test                            |
| strict      | Use strict interpretation in two-sided case       |

**Details**

Exactly one of the parameters n, delta, power, sd, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that the last two have non-NULL defaults so NULL must be explicitly passed if you want to compute them.

If strict = TRUE is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

**Value**

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

**Note**

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

**Author(s)**

Peter Dalgaard. Based on previous work by Claus Ekstrøm

**See Also**

[t.test](#), [uniroot](#)

**Examples**

```
power.t.test(n = 20, delta = 1)
power.t.test(power = .90, delta = 1)
power.t.test(power = .90, delta = 1, alternative = "one.sided")
```

**PP.test**

*Phillips-Perron Test for Unit Roots*

**Description**

Computes the Phillips-Perron test for the null hypothesis that  $x$  has a unit root against a stationary alternative.

**Usage**

```
PP.test(x, lshort = TRUE)
```

**Arguments**

- |                     |                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------|
| <code>x</code>      | a numeric vector or univariate time series.                                                     |
| <code>lshort</code> | a logical indicating whether the short or long version of the truncation lag parameter is used. |

**Details**

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate  $\sigma^2$  the Newey-West estimator is used. If `lshort` is `TRUE`, then the truncation lag parameter is set to `trunc(4*(n/100)^0.25)`, otherwise `trunc(12*(n/100)^0.25)` is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee *et al.* (1993).

Missing values are not handled.

**Value**

A list with class "htest" containing the following components:

|                        |                                                                |
|------------------------|----------------------------------------------------------------|
| <code>statistic</code> | the value of the test statistic.                               |
| <code>parameter</code> | the truncation lag parameter.                                  |
| <code>p.value</code>   | the p-value of the test.                                       |
| <code>method</code>    | a character string indicating what type of test was performed. |
| <code>data.name</code> | a character string giving the name of the data.                |

**Author(s)**

A. Trapletti

**References**

- A. Banerjee, J. J. Dolado, J. W. Galbraith, and D. F. Hendry (1993) *Cointegration, Error Correction, and the Econometric Analysis of Non-Stationary Data*, Oxford University Press, Oxford.
- P. Perron (1988) Trends and random walks in macroeconomic time series. *Journal of Economic Dynamics and Control* **12**, 297–332.

**Examples**

```
x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)
```

**Description**

Generates the sequence of probability points  $(1:m - a)/(m + (1-a)-a)$  where  $m$  is either  $n$ , if  $\text{length}(n)==1$ , or  $\text{length}(n)$ .

**Usage**

```
ppoints(n, a = ifelse(n <= 10, 3/8, 1/2))
```

**Arguments**

|                |                                                                    |
|----------------|--------------------------------------------------------------------|
| <code>n</code> | either the number of points generated or a vector of observations. |
| <code>a</code> | the offset fraction to be used; typically in $(0, 1)$ .            |

## Details

If  $0 < a < 1$ , the resulting values are within  $(0, 1)$  (excluding boundaries). In any case, the resulting sequence is symmetric in  $[0, 1]$ , i.e.,  $p + \text{rev}(p) == 1$ .

`ppoints()` is used in `qqplot` and `qqnorm` to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of  $a$  follows the documentation of the function of the same name in Becker *et al* (1988), and appears to have been motivated by results from Blom (1958) on approximations to expect normal order statistics (see also [quantile](#)).

## Examples

```
ppoints(4) # the same as ppoints(1:4)
ppoints(10)
ppoints(10, a = 1/2)
```

## Description

Fit a projection pursuit regression model.

## Usage

```
ppr(x, ...)

S3 method for class formula
ppr(formula, data, weights, subset, na.action,
 contrasts = NULL, ..., model = FALSE)

Default S3 method:
ppr(x, y, weights = rep(1, n),
 ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
 sm.method = c("supsmu", "spline", "gcv spline"),
 bass = 0, span = 0, df = 5, gcvpen = 1, ...)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula specifying one or more numeric response variables and the explanatory variables.                                                                                                                                                                                                                                                               |
| <code>x</code>         | numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.                                                                                                                                                                                                                  |
| <code>y</code>         | numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.                                                                                                                                                                                                                     |
| <code>nterms</code>    | number of terms to include in the final model.                                                                                                                                                                                                                                                                                                           |
| <code>data</code>      | a data frame (or similar: see <code>model.frame</code> ) from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                                                                          |
| <code>weights</code>   | a vector of weights $w_i$ for each <i>case</i> .                                                                                                                                                                                                                                                                                                         |
| <code>ww</code>        | a vector of weights for each <i>response</i> , so the fit criterion is the sum over case <i>i</i> and responses <i>j</i> of $w_i \cdot ww_j (y_{ij} - fit_{ij})^2$ divided by the sum of $w_i$ .                                                                                                                                                         |
| <code>subset</code>    | an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                                                                                   |
| <code>na.action</code> | a function to specify the action to be taken if <code>NAs</code> are found. The default action is given by <code>getOption("na.action")</code> . (NOTE: If given, this argument must be named.)                                                                                                                                                          |
| <code>contrasts</code> | the contrasts to be used when any factor explanatory variables are coded.                                                                                                                                                                                                                                                                                |
| <code>max.terms</code> | maximum number of terms to choose from when building the model.                                                                                                                                                                                                                                                                                          |
| <code>optlevel</code>  | integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.                                                                                                                                                                                                                        |
| <code>sm.method</code> | the method used for smoothing the ridge functions. The default is to use Friedman’s super smoother <code>supsmu</code> . The alternatives are to use the smoothing spline code underlying <code>smooth.spline</code> , either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV. |
| <code>bass</code>      | super smoother bass tone control used with automatic span selection (see <code>supsmu</code> ); the range of values is 0 to 10, with larger values resulting in increased smoothing.                                                                                                                                                                     |
| <code>span</code>      | super smoother span control (see <code>supsmu</code> ). The default, 0, results in automatic span selection by local cross validation. <code>span</code> can also take a value in $(0, 1]$ .                                                                                                                                                             |
| <code>df</code>        | if <code>sm.method</code> is “ <code>spline</code> ” specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.                                                                                                                                                                                                        |
| <code>gcvpen</code>    | if <code>sm.method</code> is “ <code>gcvspine</code> ” this is the penalty used in the GCV selection for each degree of freedom used.                                                                                                                                                                                                                    |
| <code>...</code>       | arguments to be passed to or from other methods.                                                                                                                                                                                                                                                                                                         |
| <code>model</code>     | logical. If true, the model frame is returned.                                                                                                                                                                                                                                                                                                           |

### Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS’s `ppreg`. This code is extremely sensitive to the compiler used.

The algorithm first adds up to `max.terms` ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until `nterms` terms are left.

The levels of optimization (argument optlevel) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are.

Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

### Value

A list with the following components, many of which are for use by the method functions.

|               |                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| call          | the matched call                                                                                                                              |
| p             | the number of explanatory variables (after any coding)                                                                                        |
| q             | the number of response variables                                                                                                              |
| mu            | the argument nterms                                                                                                                           |
| m1            | the argument max.terms                                                                                                                        |
| gof           | the overall residual (weighted) sum of squares for the selected model                                                                         |
| gofn          | the overall residual (weighted) sum of squares against the number of terms, up to max.terms. Will be invalid (and zero) for less than nterms. |
| df            | the argument df                                                                                                                               |
| edf           | if sm.method is "spline" or "gcvsspline" the equivalent number of degrees of freedom for each ridge term used.                                |
| xnames        | the names of the explanatory variables                                                                                                        |
| ynames        | the names of the response variables                                                                                                           |
| alpha         | a matrix of the projection directions, with a column for each ridge term                                                                      |
| beta          | a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms         |
| yb            | the weighted means of each response                                                                                                           |
| ys            | the overall scale factor used: internally the responses are divided by ys to have unit total weighted sum of squares.                         |
| fitted.values | the fitted values, as a matrix if q > 1.                                                                                                      |
| residuals     | the residuals, as a matrix if q > 1.                                                                                                          |
| smod          | internal work array, which includes the ridge functions evaluated at the training set points.                                                 |
| model         | (only if model = TRUE) the model frame.                                                                                                       |

### Source

Friedman (1984): converted to double precision and added interface to smoothing splines by B. D. Ripley, originally for the **MASS** package.

```

**Description**

Performs a principal components analysis on the given data matrix and returns the results as an object of class `prcomp`.

**Usage**

```
prcomp(x, ...)

S3 method for class formula
prcomp(formula, data = NULL, subset, na.action, ...)

Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,
 tol = NULL, ...)

S3 method for class prcomp
predict(object, newdata, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula with no response variable, referring only to numeric variables.                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>data</code>      | an optional data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                                                                                                                  |
| <code>subset</code>    | an optional vector used to select rows (observations) of the data matrix <code>x</code> .                                                                                                                                                                                                                                                                                                                                                                         |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <a href="#">options</a> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> .                                                                                                                                                                                                |
| <code>...</code>       | arguments passed to or from other methods. If <code>x</code> is a formula one might specify <code>scale.</code> or <code>tol</code> .                                                                                                                                                                                                                                                                                                                             |
| <code>x</code>         | a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.                                                                                                                                                                                                                                                                                                                                                        |
| <code>retx</code>      | a logical value indicating whether the rotated variables should be returned.                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>center</code>    | a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .                                                                                                                                                                                                                                |
| <code>scale.</code>    | a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with <code>S</code> , but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .                                                                                             |
| <code>tol</code>       | a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to <code>tol</code> times the standard deviation of the first component.) With the default null setting, no components are omitted. Other settings for <code>tol</code> could be <code>tol = 0</code> or <code>tol = sqrt(.Machine\$double.eps)</code> , which would omit essentially constant components. |
| <code>object</code>    | Object of class inheriting from “ <code>prcomp</code> ”                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>newdata</code>   | An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, <code>newdata</code> must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.                                                                                                      |

## Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using `eigen` on the covariance matrix. This is generally the preferred method for numerical accuracy. The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot.

Unlike `princomp`, variances are computed with the usual divisor  $N - 1$ .

Note that `scale = TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.

## Value

`prcomp` returns a list with class "prcomp" containing the following components:

- `sdev` the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).
- `rotation` the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function `princomp` returns this in the element `loadings`.
- `x` if `retx` is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the `rotation` matrix) is returned. Hence, `cov(x)` is the diagonal matrix `diag(sdev^2)`. For the formula method, `napredict()` is applied to handle the treatment of values omitted by the `na.action`.
- `center, scale` the centering and scaling used, or `FALSE`.

## Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

## Examples

```
signs are random
require(graphics)

the variances of the variables in the
USArests data vary by orders of magnitude, so scaling is appropriate
prcomp(USArrests) # inappropriate
prcomp(USArrests, scale = TRUE)
prcomp(~ Murder + Assault + Rape, data = USArrests, scale = TRUE)
plot(prcomp(USArrests))
summary(prcomp(USArrests, scale = TRUE))
biplot(prcomp(USArrests, scale = TRUE))
```

**predict***Model Predictions***Description**

`predict` is a generic function for predictions from the results of various model fitting functions. The function invokes particular *methods* which depend on the `class` of the first argument.

**Usage**

```
predict (object, ...)
```

**Arguments**

- |        |                                                          |
|--------|----------------------------------------------------------|
| object | a model object for which prediction is desired.          |
| ...    | additional arguments affecting the predictions produced. |

**Details**

Most prediction methods which are similar to those for linear models have an argument `newdata` specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in `newdata` to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package `stats` have an argument `n.ahead` specifying how many time steps ahead to predict.

Many methods have a logical argument `se.fit` saying if standard errors are to be returned.

**Value**

The form of the value returned by `predict` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

`predict.glm`, `predict.lm`, `predict.loess`, `predict.nls`, `predict.poly`, `predict.princomp`,  
`predict.smooth.spline`.

`SafePrediction` for prediction from polynomial and spline fits.

For time-series prediction, `predict.ar`, `predict.Arima`, `predict.arima0`,  
`predict.HoltWinters`, `predict.StructTS`.

## Examples

```
require(utils)

All the "predict" methods found
NB most of the methods in the standard packages are hidden.
for(fn in methods("predict"))
 try({
 f <- eval(substitute(getAnywhere(fn)$objs[[1]], list(fn = fn)))
 cat(fn, ":\n\t", deparse(args(f)), "\n")
 }, silent = TRUE)
```

predict.Arima

*Forecast from ARIMA fits*

## Description

Forecast from models fitted by [arima](#).

## Usage

```
S3 method for class Arima
predict(object, n.ahead = 1, newxreg = NULL,
 se.fit = TRUE, ...)
```

## Arguments

|         |                                                                                              |
|---------|----------------------------------------------------------------------------------------------|
| object  | The result of an <a href="#">arima</a> fit.                                                  |
| n.ahead | The number of steps ahead for which prediction is required.                                  |
| newxreg | New values of <i>xreg</i> to be used for prediction. Must have at least <i>n.ahead</i> rows. |
| se.fit  | Logical: should standard errors of prediction be returned?                                   |
| ...     | arguments passed to or from other methods.                                                   |

## Details

Finite-history prediction is used, via [KalmanForecast](#). This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

## Value

A time series of predictions, or if *se.fit* = TRUE, a list with components *pred*, the predictions, and *se*, the estimated standard errors. Both components are time series.

```
od <- options(digits = 5) # avoid too much spurious accuracy
predict(arima(lh, order = c(3,0,0)), n.ahead = 12)

(fit <- arima(USAccDeaths, order = c(0,1,1),
 seasonal = list(order = c(0,1,1))))
predict(fit, n.ahead = 6)
options(od)
```

***predict.glm****Predict Method for GLM Fits***Description**

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

**Usage**

```
S3 method for class glm
predict(object, newdata = NULL,
 type = c("link", "response", "terms"),
 se.fit = FALSE, dispersion = NULL, terms = NULL,
 na.action = na.pass, ...)
```

**Arguments**

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b>     | a fitted object of class inheriting from "glm".                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>newdata</b>    | optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.                                                                                                                                                                                                                                                                                                                                                                             |
| <b>type</b>       | the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale.<br>The value of this argument can be abbreviated. |
| <b>se.fit</b>     | logical switch indicating if standard errors are required.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>dispersion</b> | the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by <b>summary</b> applied to the object is used.                                                                                                                                                                                                                                                                                                                                                      |
| <b>terms</b>      | with type = "terms" by default all terms are returned. A character vector specifies which terms are to be returned                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>na.action</b>  | function determining what should be done with missing values in newdata. The default is to predict NA.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>...</b>        | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear (in predictions and standard errors), with residual value `NA`. See also [napredict](#).

## Value

If `se.fit = FALSE`, a vector or matrix of predictions. For `type = "terms"` this is a matrix with a column per term, and may have an attribute "constant".

If `se.fit = TRUE`, a list with components

`fit` Predictions, as for `se.fit = FALSE`.

`se.fit` Estimated standard errors.

`residual.scale` A scalar giving the square root of the dispersion used in computing the standard errors.

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

**predict.HoltWinters** *Prediction Function for Fitted Holt-Winters Models*

---

### Description

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

### Usage

```
S3 method for class HoltWinters
predict(object, n.ahead = 1, prediction.interval = FALSE,
 level = 0.95, ...)
```

### Arguments

|                                  |                                                                                                      |
|----------------------------------|------------------------------------------------------------------------------------------------------|
| <code>object</code>              | An object of class <code>HoltWinters</code> .                                                        |
| <code>n.ahead</code>             | Number of future periods to predict.                                                                 |
| <code>prediction.interval</code> | logical. If TRUE, the lower and upper bounds of the corresponding prediction intervals are computed. |
| <code>level</code>               | Confidence level for the prediction interval.                                                        |
| <code>...</code>                 | arguments passed to or from other methods.                                                           |

### Value

A time series of the predicted values. If prediction intervals are requested, a multiple time series is returned with columns `fit`, `lwr` and `upr` for the predicted values and the lower and upper bounds respectively.

predict.lm*Predict method for Linear Model Fits*

---

**Description**

Predicted values based on linear model object.

**Usage**

```
S3 method for class lm
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
 interval = c("none", "confidence", "prediction"),
 level = 0.95, type = c("response", "terms"),
 terms = NULL, na.action = na.pass,
 pred.var = res.var/weights, weights = 1, ...)
```

**Arguments**

|           |                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | Object of class inheriting from "lm"                                                                                                                                     |
| newdata   | An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.                                                     |
| se.fit    | A switch indicating if standard errors are required.                                                                                                                     |
| scale     | Scale parameter for std.err. calculation.                                                                                                                                |
| df        | Degrees of freedom for scale.                                                                                                                                            |
| interval  | Type of interval calculation.                                                                                                                                            |
| level     | Tolerance/confidence level.                                                                                                                                              |
| type      | Type of prediction (response or model term).                                                                                                                             |
| terms     | If type = "terms", which terms (default is all terms), a <b>character</b> vector.                                                                                        |
| na.action | function determining what should be done with missing values in newdata. The default is to predict NA.                                                                   |
| pred.var  | the variance(s) for future observations to be assumed for prediction intervals. See 'Details'.                                                                           |
| weights   | variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in newdata. |
| ...       | further arguments passed to or from other methods.                                                                                                                       |

**Details**

`predict.lm` produces predicted values, obtained by evaluating the regression function in the frame `newdata` (which defaults to `model.frame(object)`). If the logical `se.fit` is TRUE, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `intervals` specifies computation of confidence or prediction (tolerance) intervals at the specified `level`, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if `newdata` is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the predictions, whereas if `na.action = na.exclude` they will appear (in predictions, standard errors or interval limits), with value `NA`. See also [nапredict](#).

The prediction intervals are for a single observation at each case in `newdata` (or by default, the data used for the fit) with error variance(s) `pred.var`. This can be a multiple of `res.var`, the estimated value of  $\sigma^2$ : the default is to assume that future observations have the same error variance as those used for fitting. If `weights` is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, `weights` defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and `newdata` is given, the default is to assume constant prediction variance, with a warning.

### Value

`predict.lm` produces a vector of predictions or a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr` if `interval` is set. For `type = "terms"` this is a matrix with a column per term and may have an attribute "constant".

If `se.fit` is `TRUE`, a list with the following components is returned:

|                             |                                   |
|-----------------------------|-----------------------------------|
| <code>fit</code>            | vector or matrix as above         |
| <code>se.fit</code>         | standard error of predicted means |
| <code>residual.scale</code> | residual standard deviations      |
| <code>df</code>             | degrees of freedom for residual   |

### Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Notice that prediction variances and prediction intervals always refer to *future* observations, possibly corresponding to the same predictors as used for the fit. The variance of the *residuals* will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if `res.var` is not obtained from the fit.

```

**predict.loess***Predict Loess Curve or Surface***Description**

Predictions from a loess fit, optionally with standard errors.

**Usage**

```

S3 method for class loess
predict(object, newdata = NULL, se = FALSE,
 na.action = na.pass, ...)

```

**Arguments**

- |                  |                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b>    | an object fitted by loess.                                                                                                                                                                                |
| <b>newdata</b>   | an optional data frame in which to look for variables with which to predict, or a matrix or vector containing exactly the variables needed for prediction. If missing, the original data points are used. |
| <b>se</b>        | should standard errors be computed?                                                                                                                                                                       |
| <b>na.action</b> | function determining what should be done with missing values in data frame newdata. The default is to predict NA.                                                                                         |
| <b>...</b>       | arguments passed to or from other methods.                                                                                                                                                                |

## Details

The standard errors calculation is slower than prediction.

When the fit was made using `surface = "interpolate"` (the default), `predict.loess` will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

The default for `na.action` prior to R 2.12.0 was [na.omit](#).

## Value

If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If `se = TRUE`, a list containing components

|                             |                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fit</code>            | the predicted values.                                                                                                                      |
| <code>se</code>             | an estimated standard error for each predicted value.                                                                                      |
| <code>residual.scale</code> | the estimated scale of the residuals used in computing the standard errors.                                                                |
| <code>df</code>             | an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals. |

If `newdata` was the result of a call to [expand.grid](#), the predictions (and s.e.'s if requested) will be an array of the appropriate dimensions.

Predictions from infinite inputs will be NA since loess does not support extrapolation.

## Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

## Examples

```
cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
to get extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
```

---

predict.nls*Predicting from Nonlinear Least Squares Fits*

---

**Description**

`predict.nls` produces predicted values, obtained by evaluating the regression function in the frame `newdata`. If the logical `se.fit` is TRUE, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `intervals` specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present `se.fit` and `interval` are ignored.

**Usage**

```
S3 method for class nls
predict(object, newdata , se.fit = FALSE, scale = NULL, df = Inf,
 interval = c("none", "confidence", "prediction"),
 level = 0.95, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | An object that inherits from class <code>nls</code> .                                                                                                                                                                                                      |
| <code>newdata</code>  | A named list or data frame in which to look for variables with which to predict. If <code>newdata</code> is missing the fitted values at the original data points are returned.                                                                            |
| <code>se.fit</code>   | A logical value indicating if the standard errors of the predictions should be calculated. Defaults to FALSE. At present this argument is ignored.                                                                                                         |
| <code>scale</code>    | A numeric scalar. If it is set (with optional <code>df</code> ), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored. |
| <code>df</code>       | A positive numeric scalar giving the number of degrees of freedom for the <code>scale</code> estimate. At present this argument is ignored.                                                                                                                |
| <code>interval</code> | A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.                                                                                            |
| <code>level</code>    | A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.                                                                                                             |
| <code>...</code>      | Additional optional arguments. At present no optional arguments are used.                                                                                                                                                                                  |

**Value**

`predict.nls` produces a vector of predictions. When implemented, `interval` will produce a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr`. When implemented, if `se.fit` is TRUE, a list with the following components will be returned:

|                             |                                 |
|-----------------------------|---------------------------------|
| <code>fit</code>            | vector or matrix as above       |
| <code>se.fit</code>         | standard error of predictions   |
| <code>residual.scale</code> | residual standard deviations    |
| <code>df</code>             | degrees of freedom for residual |

**Note**

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

**See Also**

The model fitting function [nls](#), [predict](#).

**Examples**

```
require(graphics)

fm <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
predict(fm) # fitted values at observed times
Form data plot and smooth line for the predictions
opar <- par(las = 1)
plot(demand ~ Time, data = BOD, col = 4,
 main = "BOD data and fitted first-order curve",
 xlim = c(0,7), ylim = c(0, 20))
tt <- seq(0, 8, length = 101)
lines(tt, predict(fm, list(Time = tt)))
par(opar)
```

***predict.smooth.spline*   Predict from Smoothing Spline Fit****Description**

Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

**Usage**

```
S3 method for class smooth.spline
predict(object, x, deriv = 0, ...)
```

**Arguments**

|                     |                                                    |
|---------------------|----------------------------------------------------|
| <code>object</code> | a fit from <code>smooth.spline</code> .            |
| <code>x</code>      | the new values of <code>x</code> .                 |
| <code>deriv</code>  | integer; the order of the derivative required.     |
| <code>...</code>    | further arguments passed to or from other methods. |

**Value**

A list with components

|                |                                                      |
|----------------|------------------------------------------------------|
| <code>x</code> | The input <code>x</code> .                           |
| <code>y</code> | The fitted values or derivatives at <code>x</code> . |

**See Also**

[smooth.spline](#)

**Examples**

```
require(graphics)

attach(cars)
cars.spl <- smooth.spline(speed, dist, df = 6.4)

"Proof" that the derivatives are okay, by comparing with approximation
diff.quot <- function(x, y) {
 ## Difference quotient (central differences where available)
 n <- length(x); i1 <- 1:2; i2 <- (n-1):n
 c(diff(y[i1]) / diff(x[i1]), (y[-i1] - y[-i2]) / (x[-i1] - x[-i2]),
 diff(y[i2]) / diff(x[i2]))
}

xx <- unique(sort(c(seq(0, 30, by = .2), kn <- unique(speed))))
i.kn <- match(kn, xx) # indices of knots within xx
op <- par(mfrow = c(2,2))
plot(speed, dist, xlim = range(xx), main = "Smooth.spline & derivatives")
lines(pp <- predict(cars.spl, xx), col = "red")
points(kn, pp$y[i.kn], pch = 3, col = "dark red")
mtext("s(x)", col = "red")
for(d in 1:3){
 n <- length(pp$x)
 plot(pp$x, diff.quot(pp$x,pp$y), type = "l", xlab = "x", ylab = "",
 col = "blue", col.main = "red",
 main = paste0("s' ",paste(rep("", d), collapse = ""), "(x)"))
 mtext("Difference quotient approx.(last)", col = "blue")
 lines(pp <- predict(cars.spl, xx, deriv = d), col = "red")

 points(kn, pp$y[i.kn], pch = 3, col = "dark red")
 abline(h = 0, lty = 3, col = "gray")
}
detach(); par(op)
```

**Description**

Compute an object to be used for plots relating to the given model object.

**Usage**

```
preplot(object, ...)
```

**Arguments**

- |        |                                            |
|--------|--------------------------------------------|
| object | a fitted model object.                     |
| ...    | additional arguments for specific methods. |

## Details

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

## Value

An object set up to make a plot that describes object.

**princomp**

*Principal Components Analysis*

## Description

`princomp` performs a principal components analysis on the given numeric data matrix and returns the results as an object of class `princomp`.

## Usage

```
princomp(x, ...)

S3 method for class formula
princomp(formula, data = NULL, subset, na.action, ...)

Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,
 subset = rep(TRUE, nrow(as.matrix(x))), ...)

S3 method for class princomp
predict(object, newdata, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula with no response variable, referring only to numeric variables.                                                                                                                                                                                       |
| <code>data</code>      | an optional data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                   |
| <code>subset</code>    | an optional vector used to select rows (observations) of the data matrix <code>x</code> .                                                                                                                                                                       |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . |
| <code>x</code>         | a numeric matrix or data frame which provides the data for the principal components analysis.                                                                                                                                                                   |
| <code>cor</code>       | a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)                                                                    |
| <code>scores</code>    | a logical value indicating whether the score on each principal component should be calculated.                                                                                                                                                                  |

|         |                                                                                                                                                                                                                                                                                                                                                 |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| covmat  | a covariance matrix, or a covariance list as returned by <a href="#">cov.wt</a> (and <a href="#">cov.mve</a> or <a href="#">cov.mcd</a> from package <b>MASS</b> ). If supplied, this is used rather than the covariance matrix of $x$ .                                                                                                        |
| ...     | arguments passed to or from other methods. If $x$ is a formula one might specify <a href="#">cor</a> or <a href="#">scores</a> .                                                                                                                                                                                                                |
| object  | Object of class inheriting from "princomp"                                                                                                                                                                                                                                                                                                      |
| newdata | An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order. |

## Details

`princomp` is a generic function with "formula" and "default" methods.

The calculation is done using [eigen](#) on the correlation or covariance matrix, as determined by [cor](#). This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use [svd](#) on  $x$ , as is done in `prcomp`.

Note that the default calculation uses divisor  $N$  for the covariance matrix.

The [print](#) method for these objects prints the results in a nice format and the [plot](#) method produces a scree plot ([screeplot](#)). There is also a [biplot](#) method.

If  $x$  is a formula then the standard NA-handling is applied to the scores (if requested): see [napredict](#).

`princomp` only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use `prcomp`.

## Value

`princomp` returns a list with class "princomp" containing the following components:

|           |                                                                                                                                                                                                                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sdev      | the standard deviations of the principal components.                                                                                                                                                                                                                                                                                                         |
| loadings  | the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see <a href="#">loadings</a> for its print method.                                                                                                                                                                                     |
| center    | the means that were subtracted.                                                                                                                                                                                                                                                                                                                              |
| scale     | the scalings applied to each variable.                                                                                                                                                                                                                                                                                                                       |
| n.obs     | the number of observations.                                                                                                                                                                                                                                                                                                                                  |
| scores    | if <code>scores = TRUE</code> , the scores of the supplied data on the principal components. These are non-null only if $x$ was supplied, and if <code>covmat</code> was also supplied if it was a covariance list. For the formula method, <a href="#">napredict()</a> is applied to handle the treatment of values omitted by the <code>na.action</code> . |
| call      | the matched call.                                                                                                                                                                                                                                                                                                                                            |
| na.action | If relevant.                                                                                                                                                                                                                                                                                                                                                 |

## Note

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

## Examples

```
require(graphics)

The variances of the variables in the
USArests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests)) # inappropriate
princomp(USArrests, cor = TRUE) # ^= prcomp(USArrests, scale=TRUE)
Similar, but different:
The standard deviations differ by a factor of sqrt(49/50)

summary(pc.cr <- princomp(USArrests, cor = TRUE))
loadings(pc.cr) ## note that blank entries are small but not zero
plot(pc.cr) # shows a screeplot.
biplot(pc.cr)

Formula interface
princomp(~ ., data = USArrests, cor = TRUE)

NA-handling
USArrests[1, 2] <- NA
pc.cr <- princomp(~ Murder + Assault + UrbanPop,
 data = USArrests, na.action = na.exclude, cor = TRUE)
pc.cr$scores[1:5,]

(Simple) Robust PCA:
Classical:
(pc.cl <- princomp(stackloss))
Robust:
(pc.rob <- princomp(stackloss, covmat = MASS::cov.rob(stackloss)))
```

**print.power.htest**      *Print method for power calculation object*

## Description

Print object of class "power.htest" in nice layout.

## Usage

```
S3 method for class power.htest
print(x, ...)
```

**Arguments**

- x Object of class "power.htest".
- ... further arguments to be passed to or from methods.

**Details**

A power.htest object is just a named list of numbers and character strings, supplemented with method and note elements. The method is displayed as a title, the note as a footnote, and the remaining elements are given in an aligned 'name = value' format.

**Value**

none

**Author(s)**

Peter Dalgaard

print.ts

*Printing Time-Series Objects*

---

**Description**

Print method for time series objects.

**Usage**

```
S3 method for class ts
print(x, calendar, ...)
```

**Arguments**

- x a time series object.
- calendar enable/disable the display of information about month names, quarter names or year when printing. The default is TRUE for a frequency of 4 or 12, FALSE otherwise.
- ... additional arguments to [print](#).

**Details**

This is the [print](#) methods for objects inheriting from class "ts".

**See Also**

[print.ts](#).

**Examples**

```
print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
```

---

**printCoefmat***Print Coefficient Matrices*

---

**Description**

Utility function to be used in higher-level `print` methods, such as those for `summary.lm`, `summary.glm` and `anova`. The goal is to provide a flexible interface with smart defaults such that often, only `x` needs to be specified.

**Usage**

```
printCoefmat(x, digits = max(3, getOption("digits") - 2),
 signif.stars = getOption("show.signif.stars"),
 signif.legend = signif.stars,
 dig.tst = max(1, min(5, digits - 1)),
 cs.ind = 1L:k, tst.ind = k + 1L,
 zap.ind = integer(), P.values = NULL,
 has.Pvalue = nc >= 4L &&
 substr(colnames(x)[nc], 1L, 3L) == "Pr(",
 eps.Pvalue = .Machine$double.eps,
 na.print = "NA", ...)
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a numeric matrix like object, to be printed.                                                                                                                                                                                                                                                                                                       |
| <code>digits</code>        | minimum number of significant digits to be used for most numbers.                                                                                                                                                                                                                                                                                  |
| <code>signif.stars</code>  | logical; if TRUE, P-values are additionally encoded visually as ‘significance stars’ in order to help scanning of long coefficient tables. It defaults to the <code>show.signif.stars</code> slot of <code>options</code> .                                                                                                                        |
| <code>signif.legend</code> | logical; if TRUE, a legend for the ‘significance stars’ is printed provided <code>signif.stars = TRUE</code> .                                                                                                                                                                                                                                     |
| <code>dig.tst</code>       | minimum number of significant digits for the test statistics, see <code>tst.ind</code> .                                                                                                                                                                                                                                                           |
| <code>cs.ind</code>        | indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.                                                                                                                                                                                                                                    |
| <code>tst.ind</code>       | indices (integer) of column numbers for test statistics.                                                                                                                                                                                                                                                                                           |
| <code>zap.ind</code>       | indices (integer) of column numbers which should be formatted by <code>zapsmall</code> , i.e., by ‘zapping’ values close to 0.                                                                                                                                                                                                                     |
| <code>P.values</code>      | logical or NULL; if TRUE, the last column of <code>x</code> is formatted by <code>format.pval</code> as P values. If <code>P.values = NULL</code> , the default, it is set to TRUE only if <code>options("show.coef.Pvalue")</code> is TRUE and <code>x</code> has at least 4 columns and the last column name of <code>x</code> starts with "Pr". |
| <code>has.Pvalue</code>    | logical; if TRUE, the last column of <code>x</code> contains P values; in that case, it is printed if and only if <code>P.values</code> (above) is true.                                                                                                                                                                                           |
| <code>eps.Pvalue</code>    | number, ..                                                                                                                                                                                                                                                                                                                                         |
| <code>na.print</code>      | a character string to code NA values in printed output.                                                                                                                                                                                                                                                                                            |
| ...                        | further arguments for <code>print</code> .                                                                                                                                                                                                                                                                                                         |

**Value**

Invisibly returns its argument, `x`.

**Author(s)**

Martin Maechler

**See Also**

`print.summary.lm`, `format.pval`, `format`.

**Examples**

```
cmat <- cbind(rnorm(3, 10), sqrt(rchisq(3, 12)))
cmat <- cbind(cmat, cmat[, 1]/cmat[, 2])
cmat <- cbind(cmat, 2*pnorm(-cmat[, 3]))
colnames(cmat) <- c("Estimate", "Std.Err", "Z value", "Pr(>z)")
printCoefmat(cmat[, 1:3])
printCoefmat(cmat)
op <- options(show.coef.Pvalues = FALSE)
printCoefmat(cmat, digits = 2)
printCoefmat(cmat, digits = 2, P.values = TRUE)
options(op) # restore
```

---

profile

*Generic Function for Profiling Models*

---

**Description**

Investigates behavior of objective function near the solution represented by `fitted`.

See documentation on method functions for further details.

**Usage**

`profile(fitted, ...)`

**Arguments**

- |                     |                                                                 |
|---------------------|-----------------------------------------------------------------|
| <code>fitted</code> | the original fitted model object.                               |
| ...                 | additional parameters. See documentation on individual methods. |

**Value**

A list with an element for each parameter being profiled. See the individual methods for further details.

**See Also**

`profile.nls`, `profile.glm` in package **MASS**, ...

For profiling R code, see `Rprof`.

**profile.nls***Method for Profiling nls Objects***Description**

Investigates the profile log-likelihood function for a fitted model of class "nls".

**Usage**

```
S3 method for class nls
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
 delta.t = cutoff/5, ...)
```

**Arguments**

|                       |                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fitted</code>   | the original fitted model object.                                                                                                                      |
| <code>which</code>    | the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled. |
| <code>maxpts</code>   | maximum number of points to be used for profiling each parameter.                                                                                      |
| <code>alphamax</code> | highest significance level allowed for the profile t-statistics.                                                                                       |
| <code>delta.t</code>  | suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.                       |
| <code>...</code>      | further arguments passed to or from other methods.                                                                                                     |

**Details**

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

**Value**

|                                                                                                           |                                                     |
|-----------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| A list with an element for each parameter being profiled. The elements are data-frames with two variables |                                                     |
| <code>par.vals</code>                                                                                     | a matrix of parameter values for each fitted model. |
| <code>tau</code>                                                                                          | the profile t-statistics.                           |

## Examples

```
obtain the fitted object
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
get the profile for the fitted model: default level is too extreme
pr1 <- profile(fm1, alpha = 0.05)
profiled values for the two parameters
pr1$A
pr1$lrc
see also example(plot.profile.nls)
```

proj

*Projections of Models*

## Description

`proj` returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for `aov` models.

## Usage

```
proj(object, ...)

S3 method for class aov
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

S3 method for class aovlist
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

Default S3 method:
proj(object, onedf = TRUE, ...)

S3 method for class lm
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

## Arguments

|                               |                                                                                                                                                                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>           | An object of class " <code>lm</code> " or a class inheriting from it, or an object with a similar structure including in particular components <code>qr</code> and <code>effects</code> .                                                              |
| <code>onedf</code>            | A logical flag. If <code>TRUE</code> , a projection is returned for all the columns of the model matrix. If <code>FALSE</code> , the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table). |
| <code>unweighted.scale</code> | If the fit producing <code>object</code> used weights, this determines if the projections correspond to weighted or unweighted observations.                                                                                                           |
| <code>...</code>              | Swallow and ignore any other arguments.                                                                                                                                                                                                                |

## Details

A projection is given for each stratum of the object, so for `aov` models with an `Error` term the result is a list of projections.

**Value**

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (`onedf = FALSE`) or for each coefficient (`onedf = TRUE`). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the Q matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for `lm` and `aov` models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when `onedf = FALSE` the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

**Author(s)**

The design was inspired by the `S` function of the same name described in Chambers *et al.* (1992).

|           |                                           |
|-----------|-------------------------------------------|
| prop.test | <i>Test of Equal or Given Proportions</i> |
|-----------|-------------------------------------------|

---

## Description

`prop.test` can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

## Usage

```
prop.test(x, n, p = NULL,
 alternative = c("two.sided", "less", "greater"),
 conf.level = 0.95, correct = TRUE)
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.                                                                                                      |
| <code>n</code>           | a vector of counts of trials; ignored if <code>x</code> is a matrix or a table.                                                                                                                                                                                                                   |
| <code>p</code>           | a vector of probabilities of success. The length of <code>p</code> must be the same as the number of groups specified by <code>x</code> , and its elements must be greater than 0 and less than 1.                                                                                                |
| <code>alternative</code> | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise. |
| <code>conf.level</code>  | confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.                                                               |
| <code>correct</code>     | a logical indicating whether Yates' continuity correction should be applied where possible.                                                                                                                                                                                                       |

## Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If `p` is `NULL` and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by `alternative`. A confidence interval for the difference of proportions with confidence level as specified by `conf.level` and clipped to  $[-1, 1]$  is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is `NULL`, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is `p`, or `.5` if `p` is not given. The alternative is that the probability of success is less than, not equal to, or greater than `p` or `0.5`, respectively, as specified by `alternative`. A confidence interval for the

underlying proportion with confidence level as specified by `conf.level` and clipped to [0, 1] is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if `p` is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by `p`. The alternative is always "two.sided", the returned confidence interval is `NULL`, and continuity correction is never used.

### Value

A list with class "htest" containing the following components:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of Pearson's chi-squared test statistic.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>parameter</code>   | the degrees of freedom of the approximate chi-squared distribution of the test statistic.                                                                                                                                                                                                                                                                                                                                   |
| <code>p.value</code>     | the p-value of the test.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>estimate</code>    | a vector with the sample proportions <code>x/n</code> .                                                                                                                                                                                                                                                                                                                                                                     |
| <code>conf.int</code>    | a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and <code>p</code> is not given, or <code>NULL</code> otherwise. In the cases where it is not <code>NULL</code> , the returned confidence interval has an asymptotic confidence level as specified by <code>conf.level</code> , and is appropriate to the specified alternative hypothesis. |
| <code>null.value</code>  | the value of <code>p</code> if specified by the <code>null</code> , or <code>NULL</code> otherwise.                                                                                                                                                                                                                                                                                                                         |
| <code>alternative</code> | a character string describing the alternative.                                                                                                                                                                                                                                                                                                                                                                              |
| <code>method</code>      | a character string indicating the method used, and whether Yates' continuity correction was applied.                                                                                                                                                                                                                                                                                                                        |
| <code>data.name</code>   | a character string giving the names of the data.                                                                                                                                                                                                                                                                                                                                                                            |

[binom.test](#) for an *exact* test of a binomial hypothesis.

### Examples

```
heads <- rbinom(1, size = 100, prob = .5)
prop.test(heads, 100) # continuity correction TRUE by default
prop.test(heads, 100, correct = FALSE)

Data from Fleiss (1981), p. 139.
H0: The null hypothesis is that the four populations from which
the patients were drawn have the same true proportion of smokers.
A: The alternative is that this proportion is different in at
least one of the populations.
```

```
smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
prop.test(smokers, patients)
```

---

prop.trend.test      *Test for trend in proportions*

---

## Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

## Usage

```
prop.trend.test(x, n, score = seq_along(x))
```

## Arguments

|       |                  |
|-------|------------------|
| x     | Number of events |
| n     | Number of trials |
| score | Group score      |

## Value

An object of class "htest" with title, test statistic, p-value, etc.

## Note

This really should get integrated with prop.test

## Author(s)

Peter Dalgaard

[prop.test](#)

## Examples

```
smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
prop.test(smokers, patients)
prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0,0,0,1))
```

**qqnorm***Quantile-Quantile Plots***Description**

`qqnorm` is a generic function the default method of which produces a normal QQ plot of the values in `y`. `qqline` adds a line to a “theoretical”, by default normal, quantile-quantile plot which passes through the `probs` quantiles, by default the first and third quartiles.

`qqplot` produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to `qqnorm`, `qqplot` and `qqline`.

**Usage**

```
qqnorm(y, ...)
Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",
 xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
 plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, distribution = qnorm,
 probs = c(0.25, 0.75), qtype = 7, ...)

qqplot(x, y, plot.it = TRUE, xlab = deparse(substitute(x)),
 ylab = deparse(substitute(y)), ...)
```

**Arguments**

|                                                           |                                                                                                                                                          |
|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                                            | The first sample for <code>qqplot</code> .                                                                                                               |
| <code>y</code>                                            | The second or only data sample.                                                                                                                          |
| <code>xlab</code> , <code>ylab</code> , <code>main</code> | plot labels. The <code>xlab</code> and <code>ylab</code> refer to the <code>y</code> and <code>x</code> axes respectively if <code>datax = TRUE</code> . |
| <code>plot.it</code>                                      | logical. Should the result be plotted?                                                                                                                   |
| <code>datax</code>                                        | logical. Should data values be on the x-axis?                                                                                                            |
| <code>distribution</code>                                 | quantile function for reference theoretical distribution.                                                                                                |
| <code>probs</code>                                        | numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.                                            |
| <code>qtype</code>                                        | the type of quantile computation used in <code>quantile</code> .                                                                                         |
| <code>ylim</code> , ...                                   | graphical parameters.                                                                                                                                    |

**Value**

For `qqnorm` and `qqplot`, a list with components

|                |                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------|
| <code>x</code> | The <code>x</code> coordinates of the points that were/would be plotted                                       |
| <code>y</code> | The original <code>y</code> vector, i.e., the corresponding <code>y</code> coordinates <i>including NAs</i> . |

quade.test

*Quade Test*

## Description

Performs a Quade test with unreplicated blocked data.

## Usage

```
quade.test(y, ...)

Default S3 method:
quade.test(y, groups, blocks, ...)

S3 method for class formula
quade.test(formula, data, subset, na.action, ...)
```

## Arguments

|                     |                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>      | either a numeric vector of data values, or a data matrix.                                                                                                                            |
| <code>groups</code> | a vector giving the group for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one. |
| <code>blocks</code> | a vector giving the block for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one. |

|           |                                                                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula of the form $a \sim b   c$ , where $a$ , $b$ and $c$ give the data values and corresponding groups and blocks, respectively.                                                                                     |
| data      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| subset    | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| na.action | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| ...       | further arguments to be passed to or from methods.                                                                                                                                                                         |

## Details

`quade.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in  $y$  for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of  $y$  is the same in each of the groups.

If  $y$  is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA's are not allowed in groups or blocks; if  $y$  contains NA's, corresponding blocks are removed.

## Value

A list with class "htest" containing the following components:

|           |                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------|
| statistic | the value of Quade's F statistic.                                                                                       |
| parameter | a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                                                |
| method    | the character string "Quade test".                                                                                      |
| data.name | a character string giving the names of the data.                                                                        |

---

quantile*Sample Quantiles*

---

**Description**

The generic function `quantile` produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

**Usage**

```

quantile(x, ...)

Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
 names = TRUE, type = 7, ...)

```

**Arguments**

|                    |                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | numeric vector whose sample quantiles are wanted, or an object of a class for which a method has been defined (see also ‘details’). <code>NA</code> and <code>NaN</code> values are not allowed in numeric vectors unless <code>na.rm</code> is <code>TRUE</code> . |
| <code>probs</code> | numeric vector of probabilities with values in $[0, 1]$ . (Values up to ‘ <code>2e-14</code> ’ outside that range are accepted and moved to the nearby endpoint.)                                                                                                   |
| <code>na.rm</code> | logical; if true, any <code>NA</code> and <code>NaN</code> ’s are removed from <code>x</code> before the quantiles are computed.                                                                                                                                    |
| <code>names</code> | logical; if true, the result has a <code>names</code> attribute. Set to <code>FALSE</code> for speedup with many <code>probs</code> .                                                                                                                               |
| <code>type</code>  | an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.                                                                                                                                                                 |
| <code>...</code>   | further arguments passed to or from other methods.                                                                                                                                                                                                                  |

**Details**

A vector of length `length(probs)` is returned; if `names = TRUE`, it has a `names` attribute.

`NA` and `NaN` values in `probs` are propagated to the result.

The default method works with classed objects sufficiently like numeric vectors that `sort` and (not needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note that as this is in a namespace, the copy of `sort` in `base` will be used, not some S4 generic of that name. Also note that that is no check on the ‘correctly’, and so e.g. `quantile` can be applied to complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see “[POSIXt](#)”). Types 1 and 3 can be used for class “[Date](#)” and for ordered factors.

## Types

`quantile` returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in `x` at probabilities in `probs`. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by `type`, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quantiles of type  $i$  are defined by:

$$Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1}$$

where  $1 \leq i \leq 9$ ,  $\frac{j-m}{n} \leq p < \frac{j-m+1}{n}$ ,  $x_j$  is the  $j$ th order statistic,  $n$  is the sample size, the value of  $\gamma$  is a function of  $j = \lfloor np + m \rfloor$  and  $g = np + m - j$ , and  $m$  is a constant determined by the sample quantile type.

### Discontinuous sample quantile types 1, 2, and 3

For types 1, 2 and 3,  $Q_i(p)$  is a discontinuous function of  $p$ , with  $m = 0$  when  $i = 1$  and  $i = 2$ , and  $m = -1/2$  when  $i = 3$ .

**Type 1** Inverse of empirical distribution function.  $\gamma = 0$  if  $g = 0$ , and 1 otherwise.

**Type 2** Similar to type 1 but with averaging at discontinuities.  $\gamma = 0.5$  if  $g = 0$ , and 1 otherwise.

**Type 3** SAS definition: nearest even order statistic.  $\gamma = 0$  if  $g = 0$  and  $j$  is even, and 1 otherwise.

### Continuous sample quantile types 4 through 9

For types 4 through 9,  $Q_i(p)$  is a continuous function of  $p$ , with  $\gamma = g$  and  $m$  given below. The sample quantiles can be obtained equivalently by linear interpolation between the points  $(p_k, x_k)$  where  $x_k$  is the  $k$ th order statistic. Specific expressions for  $p_k$  are given below.

**Type 4**  $m = 0$ .  $p_k = \frac{k}{n}$ . That is, linear interpolation of the empirical cdf.

**Type 5**  $m = 1/2$ .  $p_k = \frac{k-0.5}{n}$ . That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

**Type 6**  $m = p$ .  $p_k = \frac{k}{n+1}$ . Thus  $p_k = E[F(x_k)]$ . This is used by Minitab and by SPSS.

**Type 7**  $m = 1 - p$ .  $p_k = \frac{k-1}{n-1}$ . In this case,  $p_k = \text{mode}[F(x_k)]$ . This is used by S.

**Type 8**  $m = (p + 1)/3$ .  $p_k = \frac{k-1/3}{n+1/3}$ . Then  $p_k \approx \text{median}[F(x_k)]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of `x`.

**Type 9**  $m = p/4 + 3/8$ .  $p_k = \frac{k-3/8}{n+1/4}$ . The resulting quantile estimates are approximately unbiased for the expected order statistics if `x` is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by R < 2.0.0.

r2dtable

*Random 2-way Tables with Given Marginals*

---

## Description

Generate random 2-way tables with given marginals using Patefield's algorithm.

## Usage

```
r2dtable(n, r, c)
```

## Arguments

- n a non-negative numeric giving the number of tables to be drawn.
- r a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as c.
- c a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

## Value

A list of length n containing the generated tables as its components.

## References

Patefield, W. M. (1981) Algorithm AS159. An efficient method of generating  $r \times c$  tables with given row and column totals. *Applied Statistics* **30**, 91–97.

## Examples

```

Fishers Tea Drinker data.
TeaTasting <-
matrix(c(3, 1, 1, 3),
 nrow = 2,
 dimnames = list(Guess = c("Milk", "Tea"),
 Truth = c("Milk", "Tea")))
Simulate permutation test for independence based on the maximum
Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
nOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals, "*") / nOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <-
 sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
Fishers exact test gives p = 0.4857 ...

```

**read.ftable**

*Manipulate Flat Contingency Tables*

## Description

Read, write and coerce ‘flat’ contingency tables.

## Usage

```

read.ftable(file, sep = "", quote = "\",
 row.var.names, col.vars, skip = 0)

write.ftable(x, file = "", quote = TRUE, append = FALSE,
 digits = getOption("digits"), ...)

S3 method for class ftable
format(x, quote = TRUE, digits = getOption("digits"),
 method = c("non.compact", "row.compact",
 "col.compact", "compact"),
 lsep = " | ", ...)

S3 method for class ftable
print(x, digits = getOption("digits"), ...)

```

## Arguments

- |                    |                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>  | either a character string naming a file or a connection which the data are to be read from or written to. <code>""</code> indicates input from the console for reading and output to the console for writing.                                                          |
| <code>sep</code>   | the field separator string. Values on each line of the file are separated by this string.                                                                                                                                                                              |
| <code>quote</code> | a character string giving the set of quoting characters for <code>read.ftable</code> ; to disable quoting altogether, use <code>quote=""</code> . For <code>write.table</code> , a logical indicating whether strings in the data will be surrounded by double quotes. |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| row.var.names | a character vector with the names of the row variables, in case these cannot be determined automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| col.vars      | a list giving the names and levels of the column variables, in case these cannot be determined automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| skip          | the number of lines of the data file to skip before beginning to read data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| x             | an object of class "ftable".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| append        | logical. If TRUE and file is the name of a file (and not a connection or " cmd"), the output from write.ftable is appended to the file. If FALSE, the contents of file will be overwritten.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| digits        | an integer giving the number of significant digits to use for (the cell entries of) x.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| method        | string specifying how the "ftable" object is formatted (and printed if used as in write.ftable() or the print method). Available methods are (see the examples):<br><b>"non.compact"</b> the default representation of an "ftable" object.<br><b>"row.compact"</b> a row-compact version without empty cells below the column labels.<br><b>"col.compact"</b> a column-compact version without empty cells to the right of the row labels.<br><b>"compact"</b> a row- and column-compact version. This may imply a row and a column label sharing the same cell. They are then separated by the string lsep. |
| lsep          | only for method = "compact", the separation string for row and column labels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ...           | further arguments to be passed to or from methods; for write() and print(), notably arguments such as method, passed to format().                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

read.ftable reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header information using skip, and providing the names of the row variables and the names and levels of the column variable using row.var.names and col.vars, respectively. See the examples below.

Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use [read.table](#) to read in the data, and create the contingency table from this using [xtabs](#).

[write.ftable](#) writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representations of contingency tables. Different versions are available via the method argument, which may be useful, for example, for constructing LaTeX tables.

## Examples

```

Agresti (1990), page 157, Table 5.8.
Not in ftable standard format, but o.k.
file <- tempfile()
cat(" Intercourse\n",
 "Race Gender Yes No\n",
 "White Male 43 134\n",
 " Female 26 149\n",
 "Black Male 29 23\n",
 " Female 22 36\n",
 file = file)
file.show(file)
ft1 <- read.ftable(file)
ft1
unlink(file)

Agresti (1990), page 297, Table 8.16.
Almost o.k., but misses the name of the row variable.
file <- tempfile()
cat(" \"Tonsil Size\"\n",
 " \"Not Enl.\" \"Enl.\" \"Greatly Enl.\"\\n",
 "Noncarriers 497 560 269\\n",
 "Carriers 19 29 24\\n",
 file = file)
file.show(file)
ft <- read.ftable(file, skip = 2,
 row.var.names = "Status",
 col.vars = list("Tonsil Size" =
 c("Not Enl.", "Enl.", "Greatly Enl.")))
ft
unlink(file)

ft22 <- ftable(Titanic, row.vars = 2:1, col.vars = 4:3)
write.ftable(ft22, quote = FALSE)
write.ftable(ft22, quote = FALSE, method="row.compact")
write.ftable(ft22, quote = FALSE, method="col.compact")
write.ftable(ft22, quote = FALSE, method="compact")

```

**rect.hclust**

*Draw Rectangles Around Hierarchical Clusters*

## Description

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

## Usage

```
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL,
 border = 2, cluster = NULL)
```

**Arguments**

|          |                                                                                                                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tree     | an object of the type produced by hclust.                                                                                                                                                                                                 |
| k, h     | Scalar. Cut the dendrogram such that either exactly k clusters are produced or by cutting at height h.                                                                                                                                    |
| which, x | A vector selecting the clusters around which a rectangle should be drawn. which selects clusters by number (from left to right in the tree), x selects clusters containing the respective horizontal coordinates. Default is which = 1:k. |
| border   | Vector with border colors for the rectangles.                                                                                                                                                                                             |
| cluster  | Optional vector with cluster memberships as returned by cutree(hclust.obj, k = k), can be specified for efficiency if already computed.                                                                                                   |

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**See Also**

[hclust](#), [identify.hclust](#).

**Examples**

```
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```

**Description**

The levels of a factor are re-ordered so that the level specified by ref is first and the others are moved down. This is useful for contr.treatment contrasts which take the first level as the reference.

**Usage**

```
relevel(x, ref, ...)
```

**Arguments**

|     |                                          |
|-----|------------------------------------------|
| x   | An unordered factor.                     |
| ref | The reference level.                     |
| ... | Additional arguments for future methods. |

**Value**

A factor of the same length as  $x$ .

**See Also**

[factor](#), [contr.treatment](#), [levels](#), [reorder](#).

**Examples**

```
warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")
summary(lm(breaks ~ wool + tension, data = warpbreaks))
```

**reorder.default***Reorder Levels of a Factor***Description**

`reorder` is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

**Usage**

```
reorder(x, ...)
Default S3 method:
reorder(x, X, FUN = mean, ...,
 order = is.ordered(x))
```

**Arguments**

|         |                                                                                                                                                                                                                       |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $x$     | An atomic vector, usually a factor (possibly ordered). The vector is treated as a categorical variable whose levels will be reordered. If $x$ is not a factor, its unique values will be used as the implicit levels. |
| $X$     | a vector of the same length as $x$ , whose subset of values for each unique level of $x$ determines the eventual order of that level.                                                                                 |
| $FUN$   | a function whose first argument is a vector and returns a scalar, to be applied to each subset of $X$ determined by the levels of $x$ .                                                                               |
| $\dots$ | optional: extra arguments supplied to $FUN$                                                                                                                                                                           |
| $order$ | logical, whether return value will be an ordered factor rather than a factor.                                                                                                                                         |

**Value**

A factor or an ordered factor (depending on the value of  $order$ ), with the order of the levels determined by  $FUN$  applied to  $X$  grouped by  $x$ . The levels are ordered such that the values returned by  $FUN$  are in increasing order. Empty levels will be dropped.

Additionally, the values of  $FUN$  applied to the subsets of  $X$  (in the original order of the levels of  $x$ ) is returned as the "scores" attribute.

**Examples**

```
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
 xlab = "Type of spray", ylab = "Insect count",
 main = "InsectSprays data", varwidth = TRUE,
 col = "lightgray")
```

---

**reorder.dendrogram**      *Reorder a Dendrogram*

---

**Description**

A method for the generic function [reorder](#).

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

**Usage**

```
S3 method for class dendrogram
reorder(x, wts, agglo.FUN = sum, ...)
```

**Arguments**

|           |                                                    |
|-----------|----------------------------------------------------|
| x         | the (dendrogram) object to be reordered            |
| wts       | numeric weights (arbitrary values) for reordering. |
| agglo.FUN | a function for weights agglomeration, see below.   |
| ...       | additional arguments                               |

**Details**

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as  $f(w_j)$  where  $f$  is `agglo.FUN` and  $w_j$  is the weight of the  $j$ -th sub branch).

**Value**

A dendrogram where each node has a further attribute `value` with its corresponding weight.

**Author(s)**

R. Gentleman and M. Maechler

**See Also**

[reorder](#).

[rev.dendrogram](#) which simply reverses the nodes' order; [heatmap](#), [cophenetic](#).

**Examples**

```
require(graphics)

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram dd")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean)")
par(op)
```

**replications**

*Number of Replications of Terms*

**Description**

Returns a vector or a list of the number of replicates for each term in the formula.

**Usage**

```
replications(formula, data = NULL, na.action)
```

**Arguments**

- |           |                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula or a terms object or a data frame.                                                                                                            |
| data      | a data frame used to find the objects in formula.                                                                                                       |
| na.action | function for handling missing values. Defaults to a na.action attribute of data, then a setting of the option na.action, or na.fail if that is not set. |

**Details**

If formula is a data frame and data is missing, formula is used for data with the formula  $\sim \dots$

Any character vectors in the formula are coerced to factors.

**Value**

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is `!is.list(replications(formula,data))`.

**Author(s)**

The design was inspired by the S function of the same name described in Chambers *et al.* (1992).

npk <- data.frame(block = gl(6,4), N = factor(N), P = factor(P),
 K = factor(K), yield = yield)
replications(~ . - yield, npk)
```

**Description**

This function reshapes a data frame between ‘wide’ format with repeated measurements in separate columns of the same record and ‘long’ format with the repeated measurements in separate records.

**Usage**

```
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
 idvar = "id", ids = 1:NROW(data),
 times = seq_along(varying[[1]]),
 drop = NULL, direction, new.row.names = NULL,
 sep = ".",
 split = if (sep == "") {
 list(regexp = "[A-Za-z][0-9]", include = TRUE)
 } else {
 list(regexp = sep, include = FALSE, fixed = TRUE)}
```

)

## Arguments

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>          | a data frame                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>varying</code>       | names of sets of variables in the wide format that correspond to single variables in long format ('time-varying'). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. In each case, the names can be replaced by indices which are interpreted as referring to <code>names(data)</code> . See 'Details' for more details and options.            |
| <code>v.names</code>       | names of variables in the long format that correspond to multiple variables in the wide format. See 'Details'.                                                                                                                                                                                                                                                                                                                  |
| <code>timevar</code>       | the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).                                                                                                                                                                                                                                                  |
| <code>idvar</code>         | Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.                                                                                                                                                                                                                                                                |
| <code>ids</code>           | the values to use for a newly created <code>idvar</code> variable in long format.                                                                                                                                                                                                                                                                                                                                               |
| <code>times</code>         | the values to use for a newly created <code>timevar</code> variable in long format. See 'Details'.                                                                                                                                                                                                                                                                                                                              |
| <code>drop</code>          | a vector of names of variables to drop before reshaping.                                                                                                                                                                                                                                                                                                                                                                        |
| <code>direction</code>     | character string, either "wide" to reshape to wide format, or "long" to reshape to long format.                                                                                                                                                                                                                                                                                                                                 |
| <code>new.row.names</code> | character or NULL: a non-null value will be used for the row names of the result.                                                                                                                                                                                                                                                                                                                                               |
| <code>sep</code>           | A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing <code>v.names</code> and <code>times</code> arguments based on the names in <code>varying</code> . If <code>sep == ""</code> , the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format. |
| <code>split</code>         | A list with three components, <code>regexp</code> , <code>include</code> , and (optionally) <code>fixed</code> . This allows an extended interface to variable name splitting. See 'Details'.                                                                                                                                                                                                                                   |

## Details

The arguments to this function are described in terms of longitudinal data, as that is the application motivating the functions. A 'wide' longitudinal dataset will have one record for each individual with some time-constant variables that occupy single columns and some time-varying variables that occupy a column for each time point. In 'long' format there will be multiple records for each individual, with some variables being constant across these records and others varying across the records. A 'long' format dataset also needs a 'time' variable identifying which time point each record comes from and an 'id' variable showing which records refer to the same person.

If the data frame resulted from a previous `reshape` then the operation can be reversed simply by `reshape(a)`. The `direction` argument is optional and the other arguments are stored as attributes on the data frame.

If `direction = "wide"` and no `varying` or `v.names` arguments are supplied it is assumed that all variables except `idvar` and `timevar` are time-varying. They are all expanded into multiple variables in wide format.

If `direction = "long"` the `varying` argument can be a vector of column names (or a corresponding index). The function will attempt to guess the `v.names` and `times` from these names. The default is variable names like `x.1, x.2`, where `sep = ". "` specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use `sep = ""`.

Variable name splitting as described above is only attempted in the case where `varying` is an atomic vector, if it is a list or a matrix, `v.names` and `times` will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if `v.names` is given explicitly. Notice that the order of variables in `varying` is like `x.1,y.1,x.2,y.2`.

The `split` argument should not usually be necessary. The `split$regexp` component is passed to either `strsplit` or `regexpr`, where the latter is used if `split$include` is TRUE, in which case the splitting occurs after the first character of the matched string. In the `strsplit` case, the separator is not included in the result, and it is possible to specify fixed-string matching using `split$fixed`.

## Value

The reshaped data frame with added attributes to simplify reshaping back to the original form.

## See Also

`stack`, `aperm`; `relist` for reshaping the result of `unlist`.

## Examples

```
summary(Indometh)
wide <- reshape(Indometh, v.names = "conc", idvar = "Subject",
 timevar = "time", direction = "wide")
wide

reshape(wide, direction = "long")
reshape(wide, idvar = "Subject", varying = list(2:12),
 v.names = "conc", direction = "long")

times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
 visit = I(rep(c("Before","After"), 4)),
 x = rnorm(4), y = runif(4))
df
reshape(df, timevar = "visit", idvar = "id", direction = "wide")
warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

unbalanced long data leads to NA fill in wide form
df2 <- df[1:7,]
df2
reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,60,50), dose1 = c(1,2,1,2),
 dose2 = c(2,1,2,1), dose4 = c(3,3,3,3))
reshape(df3, direction = "long", varying = 3:5, sep = "")

an example that isn't longitudinal data
```

```

state.x77 <- as.data.frame(state.x77)
long <- reshape(state.x77, idvar = "state", ids = row.names(state.x77),
 times = names(state.x77), timevar = "Characteristic",
 varying = list(names(state.x77)), direction = "long")

reshape(long, direction = "wide")

reshape(long, direction = "wide", new.row.names = unique(long$state))

multiple id variables
df3 <- data.frame(school = rep(1:3, each = 4), class = rep(9:10, 6),
 time = rep(c(1,1,2,2), 3), score = rnorm(12))
wide <- reshape(df3, idvar = c("school", "class"), direction = "wide")
wide
transform back
reshape(wide)

```

**residuals***Extract Model Residuals***Description**

`residuals` is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form `resid` is an alias for `residuals`. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a `residuals` method. (Note that the method is for ‘`residuals`’ and not ‘`resid`’.)

Methods can make use of `naresid` methods to compensate for the omission of missing values. The default, `nls` and `smooth.spline` methods do.

**Usage**

```
residuals(object, ...)
resid(object, ...)
```

**Arguments**

- |                     |                                                                      |
|---------------------|----------------------------------------------------------------------|
| <code>object</code> | an object for which the extraction of model residuals is meaningful. |
| ...                 | other arguments.                                                     |

**Value**

Residuals extracted from the object `object`.

runmed

*Running Medians – Robust Scatter Plot Smoothing*

**Description**

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

**Usage**

```
runmed(x, k, endrule = c("median", "keep", "constant"),
 algorithm = NULL, print.level = 0)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | numeric vector, the ‘dependent’ variable to be smoothed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| k           | integer width of median window; must be odd. Turlach had a default of $k <- 1 + 2 * \min((n-1) \%/% 2, \text{ceiling}(0.1*n))$ . Use $k = 3$ for ‘minimal’ robust smoothing eliminating isolated outliers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| endrule     | character string indicating how the values at the beginning and the end (of the data) should be treated.<br>“keep” keeps the first and last $k_2$ values at both ends, where $k_2$ is the half-bandwidth $k_2 = k \%/% 2$ , i.e., $y[j] = x[j]$ for $j \in \{1, \dots, k_2; n - k_2 + 1, \dots, n\}$ ;<br>“constant” copies $\text{median}(y[1:k_2])$ to the first values and analogously for the last ones making the smoothed ends <i>constant</i> ;<br>“median” the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see <a href="#">smoothEnds</a> . |
| algorithm   | character string (partially matching “Turlach” or “Stuetzle”) or the default NULL, specifying which algorithm should be applied. The default choice depends on $n = \text{length}(x)$ and $k$ where “Turlach” will be used for larger problems.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| print.level | integer, indicating verboseness of algorithm; should rarely be changed by average users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Details**

Apart from the end values, the result  $y = \text{runmed}(x, k)$  simply has  $y[j] = \text{median}(x[(j-k):(j+k)])$  ( $k = 2*k2+1$ ), computed very efficiently.

The two algorithms are internally entirely different:

“Turlach” is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance  $O(n \log k)$  where  $n = \text{length}(x)$  which is asymptotically optimal.

"Stuetzle" is the (older) Stuetzle–Friedman implementation which makes use of median *updating* when one observation enters and one leaves the smoothing window. While this performs as  $O(n \times k)$  which is slower asymptotically, it is considerably faster for small  $k$  or  $n$ .

Currently long vectors are only supported for algorithm = "Stuetzle".

### Value

vector of smoothed values of the same length as  $x$  with an attribute  $k$  containing (the ‘oddified’)  $k$ .

### Author(s)

Martin Maechler <maechler@stat.math.ethz.ch>, based on Fortran code from Werner Stuetzle and S-PLUS and C code from Berwin Turlach.

**rWishart***Random Wishart Distributed Matrices***Description**

Generate  $n$  random matrices, distributed according to the Wishart distribution with parameters  $\text{Sigma}$  and  $\text{df}$ ,  $W_p(\Sigma, m)$ ,  $m = \text{df}$ ,  $\Sigma = \text{Sigma}$ .

**Usage**

```
rWishart(n, df, Sigma)
```

**Arguments**

|                |                                                                                              |
|----------------|----------------------------------------------------------------------------------------------|
| $n$            | integer sample size.                                                                         |
| $df$           | numeric parameter, “degrees of freedom”.                                                     |
| $\text{Sigma}$ | positive definite ( $p \times p$ ) “scale” matrix, the matrix parameter of the distribution. |

**Details**

If  $X_1, \dots, X_m$ ,  $X_i \in \mathbf{R}^p$  is a sample of  $m$  independent multivariate Gaussians with mean (vector) 0, and covariance matrix  $\Sigma$ , the distribution of  $M = X'X$  is  $W_p(\Sigma, m)$ .

Consequently, the expectation of  $M$  is

$$E[M] = m \times \Sigma.$$

Further, if  $\text{Sigma}$  is scalar ( $p = 1$ ), the Wishart distribution is a scaled chi-squared ( $\chi^2$ ) distribution with  $\text{df}$  degrees of freedom,  $W_1(\sigma^2, m) = \sigma^2 \chi_m^2$ .

The component wise variance is

$$\text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii}\Sigma_{jj}).$$

**Value**

a numeric [array](#), say  $\text{R}$ , of dimension  $p \times p \times n$ , where each  $\text{R[, , i]}$  is a positive definite matrix, a realization of the Wishart distribution  $W_p(\Sigma, m)$ ,  $m = \text{df}$ ,  $\Sigma = \text{Sigma}$ .

`scatter.smooth`

*Scatter Plot with Smooth Curve Fitted by Loess*

## Description

Plot and add a smooth curve computed by loess to a scatter plot.

## Usage

```
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
 family = c("symmetric", "gaussian"),
 xlab = NULL, ylab = NULL,
 ylim = range(y, pred$y, na.rm = TRUE),
 evaluation = 50, ..., lpars = list())

loess.smooth(x, y, span = 2/3, degree = 1,
 family = c("symmetric", "gaussian"), evaluation = 50, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>   | the <code>x</code> and <code>y</code> arguments provide the <code>x</code> and <code>y</code> coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function <a href="#">xy.coords</a> for details. |
| <code>span</code>   | smoothness parameter for loess.                                                                                                                                                                                                               |
| <code>degree</code> | degree of local polynomial used.                                                                                                                                                                                                              |
| <code>family</code> | if "gaussian" fitting is by least-squares, and if <code>family = "symmetric"</code> a re-descending M estimator is used.                                                                                                                      |
| <code>xlab</code>   | label for x axis.                                                                                                                                                                                                                             |

|                         |                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ylab</code>       | label for y axis.                                                                                                                                                                       |
| <code>ylim</code>       | the y limits of the plot.                                                                                                                                                               |
| <code>evaluation</code> | number of points at which to evaluate the smooth curve.                                                                                                                                 |
| <code>...</code>        | For <code>scatter.smooth()</code> , graphical parameters, passed to <code>plot()</code> only. For <code>loess.smooth</code> , control parameters passed to <code>loess.control</code> . |
| <code>lpars</code>      | a <code>list</code> of arguments to be passed to <code>lines()</code> .                                                                                                                 |

## Details

`loess.smooth` is an auxiliary function which evaluates the loess smooth at `evaluation` equally spaced points covering the range of `x`.

## Value

For `scatter.smooth`, `none`.

For `loess.smooth`, a list with two components, `x` (the grid of evaluation points) and `y` (the smoothed values at the grid points).

## See Also

`loess`; `smoothScatter` for scatter plots with smoothed *density* color representation.

## Examples

```
require(graphics)

with(cars, scatter.smooth(speed, dist))
or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpars =
 list(col = "red", lwd = 3, lty = 3)))
```

## Description

`screeplot.default` plots the variances against the number of the principal component. This is also the plot method for classes "`princomp`" and "`prcomp`".

## Usage

```
Default S3 method:
screeplot(x, npcs = min(10, length(x$sdev)),
 type = c("barplot", "lines"),
 main = deparse(substitute(x)), ...)
```

**Arguments**

- x an object containing a sdev component, such as that returned by [princomp\(\)](#) and [prcomp\(\)](#).
- npcs the number of components to be plotted.
- type the type of plot.
- main, ... graphics parameters.

**References**

- Mardia, K. V., J. T. Kent and J. M. Bibby (1979). *Multivariate Analysis*, London: Academic Press.  
 Venables, W. N. and B. D. Ripley (2002). *Modern Applied Statistics with S*, Springer-Verlag.

**See Also**

[princomp](#) and [prcomp](#).

**Examples**

```
require(graphics)

The variances of the variables in the
USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE)) # inappropriate
screeplot(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screeplot(fit)
screeplot(fit, npcs = 24, type = "lines")
```

|    |                           |
|----|---------------------------|
| sd | <i>Standard Deviation</i> |
|----|---------------------------|

**Description**

This function computes the standard deviation of the values in x. If na.rm is TRUE then missing values are removed before computation proceeds.

**Usage**

```
sd(x, na.rm = FALSE)
```

**Arguments**

- x a numeric vector or an R object which is coercible to one by `as.vector(x, "numeric")`.
- na.rm logical. Should missing values be removed?

## Details

Like [var](#) this uses denominator  $n - 1$ .

The standard deviation of a zero-length vector (after removal of NAs if `na.rm = TRUE`) is not defined and gives an error. The standard deviation of a length-one vector is NA.

Prior to R 2.14.0, `sd(dfrm)` worked directly for a [data.frame](#) `dfrm`. This is now defunct and you are expected to use [sapply\(dfrm, sd\)](#).

## See Also

[var](#) for its square, and [mad](#), the most robust alternative.

## Examples

```
sd(1:2) ^ 2
```

---

se.contrast

*Standard Errors for Contrasts in Model Terms*

---

## Description

Returns the standard errors for one or more contrasts in an `aov` object.

## Usage

```
se.contrast(object, ...)
S3 method for class aov
se.contrast(object, contrast.obj,
 coef = contr.helmert(ncol(contrast))[, 1],
 data = NULL, ...)
```

## Arguments

- |                           |                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | A suitable fit, usually from <code>aov</code> .                                                                                                                                                                                                                                                                                        |
| <code>contrast.obj</code> | The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero). |
| <code>coef</code>         | used when <code>contrast.obj</code> is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.                                                                                             |
| <code>data</code>         | The data frame used to evaluate <code>contrast.obj</code> .                                                                                                                                                                                                                                                                            |
| ...                       | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                     |

## Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use `se.contrast` than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for `aov` about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with `coef` can be found by calling `contrasts` and indexing the columns by a factor.

## Value

A vector giving the standard errors for each contrast.

## See Also

`contrasts`, `model.tables`

## Examples

```

summary(fit2)$tTable # same estimates, similar (but smaller) ses.

End(Not run)

```

## Description

Construct self-starting nonlinear models.

## Usage

```
selfStart(model, initial, parameters, template)
```

## Arguments

- |                   |                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>model</b>      | a function object defining a nonlinear model or a nonlinear formula object of the form $\sim$ expression.                                                                                                                                                                                                                                                                                                         |
| <b>initial</b>    | a function object, taking three arguments: mCall, data, and LHS, representing, respectively, a matched call to the function <code>model</code> , a data frame in which to interpret the variables in <code>mCall</code> , and the expression from the left-hand side of the model formula in the call to <code>nls</code> . This function should return initial values for the parameters in <code>model</code> . |
| <b>parameters</b> | a character vector specifying the terms on the right hand side of <code>model</code> for which initial estimates should be calculated. Passed as the <code>namevec</code> argument to the <code>deriv</code> function.                                                                                                                                                                                            |
| <b>template</b>   | an optional prototype for the calling sequence of the returned object, passed as the <code>function.arg</code> argument to the <code>deriv</code> function. By default, a template is generated with the covariates in <code>model</code> coming first and the parameters in <code>model</code> coming last in the calling sequence.                                                                              |

## Details

This function is generic; methods functions can be written to handle specific classes of objects.

## Value

a function object of class "selfStart", for the formula method obtained by applying `deriv` to the right hand side of the model formula. An `initial` attribute (defined by the `initial` argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

## Author(s)

José Pinheiro and Douglas Bates

## See Also

`nls`, `getInitial`. Each of the following are "selfStart" models (with examples) `SSasymp`, `SSasympOff`, `SSasympOrig`, `SSbiexp`, `SSfol`, `SSfp1`, `SSgompertz`, `SSlogis`, `SSmicmen`, `SSweibull`

## Examples

```
self-starting logistic model

SSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
 function(mCall, data, LHS)
{
 xy <- sortedXYData(mCall[["x"]], LHS, data)
 if(nrow(xy) < 4) {
 stop("Too few distinct x values to fit a logistic")
 }
 z <- xy[["y"]]
 if (min(z) <= 0) { z <- z + 0.05 * max(z) } # avoid zeroes
 z <- z/(1.05 * max(z)) # scale to within unit height
 xy[["z"]] <- log(z/(1 - z)) # logit transformation
 aux <- coef(lm(x ~ z, xy))
 parameters(xy) <- list(xmid = aux[1], scal = aux[2])
 pars <- as.vector(coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
 data = xy, algorithm = "plinear")))
 setNames(c(pars[3], pars[1], pars[2]),
 mCall[c("Asym", "xmid", "scal")])
}, c("Asym", "xmid", "scal"))

first.order.log.model is a function object defining a first order
compartment model
first.order.log.initial is a function object which calculates initial
values for the parameters in first.order.log.model

self-starting first order compartment model
Not run:
SSfol <- selfStart(first.order.log.model, first.order.log.initial)

End(Not run)

Explore the self-starting models already available in R's "stats":
pos.st <- which("package:stats" == search())
mSS <- apropos("^SS..", where = TRUE, ignore.case = FALSE)
```

```
(mSS <- unname(mSS[names(mSS) == pos.st]))
fSS <- sapply(mSS, get, pos = pos.st, mode = "function")
all(sapply(fSS, inherits, "selfStart")) # -> TRUE

Show the argument list of each self-starting function:
str(fSS, give.attr = FALSE)
```

---

**setNames***Set the Names in an Object*

---

**Description**

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.

**Usage**

```
setNames(object = nm, nm)
```

**Arguments**

|        |                                                          |
|--------|----------------------------------------------------------|
| object | an object for which a names attribute will be meaningful |
| nm     | a character vector of names to assign to the object      |

**Value**

An object of the same sort as object with the new names assigned.

**Author(s)**

Douglas M. Bates and Saikat DebRoy

**See Also**

[unname](#) for removing names.

**Examples**

```
setNames(1:3, c("foo", "bar", "baz"))
this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp

special case of character vector, using default
setNames(nm = c("First", "2nd"))
```

---

**shapiro.test** *Shapiro-Wilk Normality Test*

---

**Description**

Performs the Shapiro-Wilk test of normality.

**Usage**

```
shapiro.test(x)
```

**Arguments**

**x** a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000.

**Value**

A list with class "htest" containing the following components:

|                  |                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------|
| <b>statistic</b> | the value of the Shapiro-Wilk statistic.                                                                 |
| <b>p.value</b>   | an approximate p-value for the test. This is said in Royston (1995) to be adequate for $p.value < 0.1$ . |
| <b>method</b>    | the character string "Shapiro-Wilk normality test".                                                      |
| <b>data.name</b> | a character string giving the name(s) of the data.                                                       |

**Source**

The algorithm used is a C translation of the Fortran code described in Royston (1995) and found at <http://lib.stat.cmu.edu/apstat/R94>. The calculation of the p value is exact for  $n = 3$ , otherwise approximations are used, separately for  $4 \leq n \leq 11$  and  $n \geq 12$ .

[qqnorm](#) for producing a normal quantile-quantile plot.

**Examples**

```
shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
```

---

SignRank*Distribution of the Wilcoxon Signed Rank Statistic*

---

**Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size n.

**Usage**

```
dsignrank(x, n, log = FALSE)
psignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qsignrank(p, n, lower.tail = TRUE, log.p = FALSE)
rsignrank(nn, n)
```

**Arguments**

|            |                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------|
| x, q       | vector of quantiles.                                                                                       |
| p          | vector of probabilities.                                                                                   |
| nn         | number of observations. If <code>length(nn) &gt; 1</code> , the length is taken to be the number required. |
| n          | number(s) of observations in the sample(s). A positive integer, or a vector of such integers.              |
| log, log.p | logical; if TRUE, probabilities p are given as log(p).                                                     |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                      |

**Details**

This distribution is obtained as follows. Let x be a sample of size n from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values  $x[i]$  for which  $x[i]$  is positive. This statistic takes values between 0 and  $n(n + 1)/2$ , and its mean and variance are  $n(n + 1)/4$  and  $n(n + 1)(2n + 1)/24$ , respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

**Value**

`dsignrank` gives the density, `psignrank` gives the distribution function, `qsignrank` gives the quantile function, and `rsignrank` generates random deviates.

The length of the result is determined by `nn` for `rsignrank`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `nn` are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Author(s)**

Kurt Hornik; efficiency improvement by Ivo Ugrina.

**Examples**

```
require(graphics)

par(mfrow = c(2,2))
for(n in c(4:5,10,40)) {
 x <- seq(0, n*(n+1)/2, length = 501)
 plot(x, dsignrank(x, n = n), type = "l",
 main = paste0("dsignrank(x, n = ", n, ")"))
}
```

---

**simulate**

*Simulate Responses*

---

**Description**

Simulate one or more responses from the distribution corresponding to a fitted model object.

**Usage**

```
simulate(object, nsim = 1, seed = NULL, ...)
```

**Arguments**

- |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object representing a fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| nsim   | number of response vectors to simulate. Defaults to 1.                                                                                                                                                                                                                                                                                                                                                                                                             |
| seed   | an object specifying if and how the random number generator should be initialized ('seeded').<br>For the "lm" method, either NULL or an integer that will be used in a call to <code>set.seed</code> before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return <a href="#">.Random.seed</a> as the "seed" attribute, see 'Value'. |
| ...    | additional optional arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Details**

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package **stats** has a method for "lm" objects which is used for [lm](#) and [glm](#) fits. There is a method for fits from [glm.nb](#) in package **MASS**, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by [lm](#) or [glm\(family = "gaussian"\)](#) assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs

the (optional) `simulate` component of the `family` object is used—there is no appropriate simulation method for ‘quasi’ models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights  $w_i$  can be interpreted as meaning that observation  $i$  is an average of  $w_i$  observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function `gamma.shape` in package **MASS**). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.

For an inverse gaussian GLM the model assumed is  $IG(\mu_i, \lambda w_i)$  (see [http://en.wikipedia.org/wiki/Inverse\\_Gaussian\\_distribution](http://en.wikipedia.org/wiki/Inverse_Gaussian_distribution)) where  $\lambda$  is estimated by the inverse of the dispersion estimate for the fit. The variance is  $\mu_i^3 / (\lambda w_i)$  and hence inversely proportional to the prior weights. The simulation is done by function `rinvGauss` from the **SuppDists** package, which must be installed.

## Value

Typically, a list of length `nsim` of simulated responses. Where appropriate the result can be a data frame (which is a special type of list).

For the “`lm`” method, the result is a data frame with an attribute “seed”. If argument `seed` is `NULL`, the attribute is the value of `.Random.seed` before the simulation was started; otherwise it is the value of the argument with a “kind” attribute with value `as.list(RNGkind())`.

## See Also

`RNG` about random number generation in R, `fitted.values` and `residuals` for related methods; `glm`, `lm` for model fitting.

There are further examples in the ‘simulate.R’ tests file in the sources for package **stats**.

## Examples

```
x <- 1:5
mod1 <- lm(c(1:3, 7, 6) ~ x)
S1 <- simulate(mod1, nsim = 4)
repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about the same as
fitted(mod1)

repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))

Binomial GLM examples
```

```

yb1 <- matrix(c(4, 4, 5, 7, 8, 6, 6, 5, 3, 2), ncol = 2)
modb1 <- glm(yb1 ~ x, family = binomial)
S3 <- simulate(modb1, nsim = 4)
each column of S3 is a two-column matrix.

x2 <- sort(runif(100))
yb2 <- rbinom(100, prob = plogis(2*(x2-1)), size = 1)
yb2 <- factor(1 + yb2, labels = c("failure", "success"))
modb2 <- glm(yb2 ~ x2, family = binomial)
S4 <- simulate(modb2, nsim = 4)
each column of S4 is a factor

```

smooth

*Tukey's (Running Median) Smoothing*

## Description

Tukey's smoothers, *3RS3R*, *3RSS*, *3R*, etc.

## Usage

```
smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
 twiceit = FALSE, endrule = "Tukey", do.ends = FALSE)
```

## Arguments

|                      |                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>       | a vector or time series                                                                                                                                                                                         |
| <code>kind</code>    | a character string indicating the kind of smoother required; defaults to "3RS3R".                                                                                                                               |
| <code>twiceit</code> | logical, indicating if the result should be 'twiced'. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$ , i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance). |
| <code>endrule</code> | a character string indicating the rule for smoothing at the boundary. Either "Tukey" (default) or "copy".                                                                                                       |
| <code>do.ends</code> | logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for <code>kind = "S"</code> .                                                                     |

## Details

`3` is Tukey's short notation for running `medians` of length **3**,  
`3R` stands for **R**epeated `3` until convergence, and  
`S` for **S**plitting of horizontal stretches of length 2 or 3.

Hence, `3RS3R` is a concatenation of `3R`, `S` and `3R`, `3RSS` similarly, whereas `3RSR` means first `3R` and then (`S` and `3`) **R**epeated until convergence – which can be bad.

## Value

An object of class "`tukeysmooth`" (which has `print` and `summary` methods) and is a vector or time series containing the smoothed values with additional attributes.

### Note

S and S-PLUS use a different (somewhat better) Tukey smoother in `smooth(*)`. Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.

Since R version 1.2, `smooth` does really implement Tukey's end-point rule correctly (see argument `endrule`).

`kind = "3RSR"` has been the default till R-1.1, but it can have very bad properties, see the examples.

Note that repeated application of `smooth(*)` does smooth more, for the "3RS\*" kinds.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | a vector giving the values of the predictor variable, or a list or a two-column matrix specifying <code>x</code> and <code>y</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>y</code>            | responses. If <code>y</code> is missing or <code>NULL</code> , the responses are assumed to be specified by <code>x</code> , with <code>x</code> the index vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>w</code>            | optional vector of weights of the same length as <code>x</code> ; defaults to all 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>df</code>           | the desired equivalent number of degrees of freedom (trace of the smoother matrix).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>spar</code>         | smoothing parameter, typically (but not necessarily) in $(0, 1]$ . The coefficient $\lambda$ of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of <code>spar</code> , see the details below.                                                                                                                                                                                                                                                                                                                                                         |
| <code>cv</code>           | ordinary (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE; setting it to NA skips the evaluation of leverages and any score.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>all.knots</code>    | if TRUE, all distinct points in <code>x</code> are used as knots. If FALSE (default), a subset of <code>x[]</code> is used, specifically <code>x[j]</code> where the <code>nknots</code> indices are evenly spaced in <code>1:n</code> , see also the next argument <code>nknots</code> .                                                                                                                                                                                                                                                                                                                                  |
| <code>nknots</code>       | integer giving the number of knots to use when <code>all.knots = FALSE</code> . Per default, this is less than $n$ , the number of unique <code>x</code> values for $n > 49$ .                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>keep.data</code>    | logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>df.offset</code>    | allows the degrees of freedom to be increased by <code>df.offset</code> in the GCV criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>penalty</code>      | the coefficient of the penalty for degrees of freedom in the GCV criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>control.spar</code> | optional list with named components controlling the root finding when the smoothing parameter <code>spar</code> is computed, i.e., missing or <code>NULL</code> , see below.<br><b>Note</b> that this is partly <i>experimental</i> and may change with general <code>spar</code> computation improvements!<br><b>low:</b> lower bound for <code>spar</code> ; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).<br><b>high:</b> upper bound for <code>spar</code> ; defaults to +1.5.<br><b>tol:</b> the absolute precision ( <b>tolerance</b> ) used; defaults to 1e-4 (formerly 1e-3). |

**eps:** the relative precision used; defaults to 2e-8 (formerly 0.00244).

**trace:** logical indicating if iterations should be traced.

**maxit:** integer giving the maximal number of iterations; defaults to 500.

Note that `spar` is only searched for in the interval  $[low, high]$ .

**tol** A tolerance for same-ness of the `x` values. The values are binned into bins of size `tol` and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).

## Details

Neither `x` nor `y` are allowed to contain missing or infinite values.

The `x` vector should contain at least four distinct values. ‘Distinct’ here is controlled by `tol`: values which are regarded as the same are replaced by the first of their values and the corresponding `y` and `w` are pooled accordingly.

The computational  $\lambda$  used (as a function of  $s = spar$ ) is  $\lambda = r * 256^{3s-1}$  where  $r = \text{tr}(X'WX)/\text{tr}(\Sigma)$ ,  $\Sigma$  is the matrix given by  $\Sigma_{ij} = \int B_i''(t)B_j''(t)dt$ ,  $X$  is given by  $X_{ij} = B_j(x_i)$ ,  $W$  is the diagonal matrix of weights (scaled such that its trace is  $n$ , the original number of observations) and  $B_k(\cdot)$  is the  $k$ -th B-spline.

Note that with these definitions,  $f_i = f(x_i)$ , and the B-spline basis representation  $f = Xc$  (i.e., `c` is the vector of spline coefficients), the penalized log likelihood is  $L = (y - f)'W(y - f) + \lambda c'\Sigma c$ , and hence `c` is the solution of the (ridge regression)  $(X'WX + \lambda\Sigma)c = X'Wy$ .

If `spar` is missing or `NULL`, the value of `df` is used to determine the degree of smoothing. If both are missing, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by `cv`) is used to determine  $\lambda$ . Note that from the above relation,

`spar` is  $s = s0 + 0.0601 * \log \lambda$ , which is intentionally *different* from the S-PLUS implementation of `smooth.spline` (where `spar` is proportional to  $\lambda$ ). In R’s ( $\log \lambda$ ) scale, it makes more sense to vary `spar` linearly.

Note however that currently the results may become very unreliable for `spar` values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting `spar` or the controls `low` and `high` outside such a safe range, unless you know what you are doing!

The ‘generalized’ cross-validation method will work correctly when there are duplicated points in `x`. However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. `cv = TRUE` is best avoided in that case.

## Value

An object of class “`smooth.spline`” with components

- `x` the *distinct* `x` values in increasing order, see the ‘Details’ above.
- `y` the fitted values corresponding to `x`.
- `w` the weights used at the unique values of `x`.
- `yin` the `y` values used at the unique `y` values.
- `data` only if `keep.data = TRUE`: itself a `list` with components `x`, `y` and `w` of the same length. These are the original  $(x_i, y_i, w_i), i = 1, \dots, n$ , values where `data$x` may have repeated values and hence be longer than the above `x` component; see details.
- `lev` (when `cv` was not `NA`) leverages, the diagonal values of the smoother matrix.

|                       |                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cv.crit</code>  | cross-validation score, ‘generalized’ or true, depending on <code>cv</code> .                                                                                                                                                                                                                                                                                                                      |
| <code>pen.crit</code> | penalized criterion                                                                                                                                                                                                                                                                                                                                                                                |
| <code>crit</code>     | the criterion value minimized in the underlying .Fortran routine ‘ <code>sslvg</code> ’.                                                                                                                                                                                                                                                                                                           |
| <code>df</code>       | equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true <code>df</code> is between 1 and 2.                                                                                                                                                                                                                                                  |
| <code>spar</code>     | the value of <code>spar</code> computed or given.                                                                                                                                                                                                                                                                                                                                                  |
| <code>lambda</code>   | the value of $\lambda$ corresponding to <code>spar</code> , see the details above.                                                                                                                                                                                                                                                                                                                 |
| <code>iparms</code>   | named integer(3) vector where <code>..\$ipars["iter"]</code> gives number of <code>spar</code> computing iterations used.                                                                                                                                                                                                                                                                          |
| <code>fit</code>      | list for use by <code>predict.smooth.spline</code> , with components<br><code>knot</code> : the knot sequence (including the repeated boundary knots).<br><code>nk</code> : number of coefficients or number of ‘proper’ knots plus 2.<br><code>coef</code> : coefficients for the spline basis used.<br><code>min, range</code> : numbers giving the corresponding quantities of <code>x</code> . |
| <code>call</code>     | the matched call.                                                                                                                                                                                                                                                                                                                                                                                  |

### Note

The default `all.knots = FALSE` and `nknots = NULL` entails using only  $O(n^{0.2})$  knots instead of  $n$  for  $n > 49$ . This cuts speed and memory requirements, but not drastically anymore since R version 1.5.1 where it is only  $O(n_k) + O(n)$  where  $n_k$  is the number of knots. In this case where not all unique `x` values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large `df`) is used.

### Author(s)

R implementation by B. D. Ripley and Martin Maechler (`spar`/`lambda`, etc).

### Source

This function is based on code in the GAMFIT Fortran program by T. Hastie and R. Tibshirani (<http://lib.stat.cmu.edu/general/>), which makes use of spline code by Finbarr O’Sullivan. Its design parallels the `smooth.spline` function of Chambers & Hastie (1992).

`predict.smooth.spline` for evaluating the spline and its derivatives.

## Examples

```

require(graphics)

attach(cars)
plot(speed, dist, main = "data(cars) & smoothing splines")
cars.spl <- smooth.spline(speed, dist)
(cars.spl)
This example has duplicate points, so avoid cv = TRUE

lines(cars.spl, col = "blue")
lines(smooth.spline(speed, dist, df = 10), lty = 2, col = "red")
legend(5,120,c(paste("default [C.V.] => df =",round(cars.spl$df,1)),
 "s(* , df = 10)'), col = c("blue","red"), lty = 1:2,
 bg = bisque)
detach()

Residual (Tukey Anscombe) plot:
plot(residuals(cars.spl) ~ fitted(cars.spl))
abline(h = 0, col = "gray")

consistency check:
stopifnot(all.equal(cars$dist,
 fitted(cars.spl) + residuals(cars.spl)))

##-- artificial example
y18 <- c(1:3, 5, 4, 7:3, 2*(2:5), rep(10, 4))
xx <- seq(1, length(y18), len = 201)
(s2 <- smooth.spline(y18)) # GCV
(s02 <- smooth.spline(y18, spar = 0.2))
(s02. <- smooth.spline(y18, spar = 0.2, cv = NA))
plot(y18, main = deparse(s2$call), col.main = 2)
lines(s2, col = "gray"); lines(predict(s2, xx), col = 2)
lines(predict(s02, xx), col = 3); mtext(deparse(s02$call), col = 3)

The following shows the problematic behavior of spar searching:
(s2 <- smooth.spline(y18, control =
 list(trace = TRUE, tol = 1e-6, low = -1.5)))
(s2m <- smooth.spline(y18, cv = TRUE, control =
 list(trace = TRUE, tol = 1e-6, low = -1.5)))
both above do quite similarly (Df = 8.5 +- 0.2)

```

smoothEnds

*End Points Smoothing (for Running Medians)*

## Description

Smooth end points of a vector  $y$  using subsequently smaller medians and Tukey's end point rule at the very end. (of odd span),

## Usage

```
smoothEnds(y, k = 3)
```

### Arguments

- y dependent variable to be smoothed (vector).  
k width of largest median window; must be odd.

### Details

`smoothEnds` is used to only do the ‘end point smoothing’, i.e., change at most the observations closer to the beginning/end than half the window k. The first and last value are computed using Tukey’s *end point rule*, i.e.,  $\text{sm}[1] = \text{median}(y[1], \text{sm}[2], 3*\text{sm}[2] - 2*\text{sm}[3])$ .

### Value

vector of smoothed values, the same length as y.

### Author(s)

Martin Maechler

### References

Velleman, P.F., and Hoaglin, D.C. (1981) *ABC of EDA (Applications, Basics, and Computing of Exploratory Data Analysis)*; Duxbury.

### See Also

`runmed`(\* , endrule = "median") which calls `smoothEnds()`.

### Examples

```
require(graphics)

y <- ys <- (-20:20)^2
y [c(1,10,21,41)] <- c(100, 30, 400, 470)
s7k <- runmed(y, 7, endrule = "keep")
s7. <- runmed(y, 7, endrule = "const")
s7m <- runmed(y, 7)
col3 <- c("midnightblue", "blue", "steelblue")
plot(y, main = "Running Medians -- runmed(*, k=7, end.rule = X)")
lines(ys, col = "light gray")
matlines(cbind(s7k, s7., s7m), lwd = 1.5, lty = 1, col = col3)
legend(1, 470, paste("endrule", c("keep", "constant", "median"), sep = " = "),
 col = col3, lwd = 1.5, lty = 1)

stopifnot(identical(s7m, smoothEnds(s7k, 7)))
```

sortedXyData

*Create a sortedXyData Object***Description**

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the `initial` function for a self-starting nonlinear regression model, which will be of the `selfStart` class.

**Usage**

```
sortedXyData(x, y, data)
```

**Arguments**

|                   |                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | a numeric vector or an expression that will evaluate in <code>data</code> to a numeric vector                                    |
| <code>y</code>    | a numeric vector or an expression that will evaluate in <code>data</code> to a numeric vector                                    |
| <code>data</code> | an optional data frame in which to evaluate expressions for <code>x</code> and <code>y</code> , if they are given as expressions |

**Value**

A `sortedXyData` object. This is a data frame with exactly two numeric columns, named `x` and `y`. The rows are sorted so the `x` column is in increasing order. Duplicate `x` values are eliminated by averaging the corresponding `y` values.

**Author(s)**

José Pinheiro and Douglas Bates

**Examples**

```
DNase.2 <- DNase[DNase$Run == "2",]
sortedXyData(expression(log(conc)), expression(density), DNase.2)
```

spec.ar

*Estimate Spectral Density of a Time Series from AR Fit***Description**

Fits an AR model to `x` (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

**Usage**

```
spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail,
 method = "yule-walker", ...)
```

### Arguments

|           |                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------|
| x         | A univariate (not yet:or multivariate) time series or the result of a fit by <a href="#">ar</a> . |
| n.freq    | The number of points at which to plot.                                                            |
| order     | The order of the AR model to be fitted. If omitted, the order is chosen by AIC.                   |
| plot      | Plot the periodogram?                                                                             |
| na.action | NA action function.                                                                               |
| method    | method for <a href="#">ar</a> fit.                                                                |
| ...       | Graphical arguments passed to <a href="#">plot.spec</a> .                                         |

### Value

An object of class "spec". The result is returned invisibly if plot is true.

### Warning

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

### Note

The multivariate case is not yet implemented.

spec.ar(ldeaths)
spec.ar(ldeaths, method = "burg")

spec.ar(log(lynx))
spec.ar(log(lynx), method = "burg", add = TRUE, col = "purple")
spec.ar(log(lynx), method = "mle", add = TRUE, col = "forest green")
spec.ar(log(lynx), method = "ols", add = TRUE, col = "blue")
```

spec.pgram

*Estimate Spectral Density of a Time Series by a Smoothed Periodogram***Description**

`spec.pgram` calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

**Usage**

```
spec.pgram(x, spans = NULL, kernel, taper = 0.1,
 pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE,
 plot = TRUE, na.action = na.fail, ...)
```

**Arguments**

|                        |                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | univariate or multivariate time series.                                                                                                                |
| <code>spans</code>     | vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.                                           |
| <code>kernel</code>    | alternatively, a kernel smoother of class "tskernel".                                                                                                  |
| <code>taper</code>     | specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series. |
| <code>pad</code>       | proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion <code>pad</code> .                        |
| <code>fast</code>      | logical; if <code>TRUE</code> , pad the series to a highly composite length.                                                                           |
| <code>demean</code>    | logical. If <code>TRUE</code> , subtract the mean of the series.                                                                                       |
| <code>detrend</code>   | logical. If <code>TRUE</code> , remove a linear trend from the series. This will also remove the mean.                                                 |
| <code>plot</code>      | plot the periodogram?                                                                                                                                  |
| <code>na.action</code> | NA action function.                                                                                                                                    |
| <code>...</code>       | graphical arguments passed to <code>plot.spec</code> .                                                                                                 |

**Details**

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the `fast` and not the `pad` argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

**Value**

A list object of class "spec" (see [spectrum](#)) with the following additional components:

|                        |                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kernel</code>    | The kernel argument, or the kernel constructed from spans.                                                                                           |
| <code>df</code>        | The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with <code>df</code> degrees of freedom. |
| <code>bandwidth</code> | The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).                                                           |
| <code>taper</code>     | The value of the <code>taper</code> argument.                                                                                                        |
| <code>pad</code>       | The value of the <code>pad</code> argument.                                                                                                          |
| <code>detrend</code>   | The value of the <code>detrend</code> argument.                                                                                                      |
| <code>demean</code>    | The value of the <code>demean</code> argument.                                                                                                       |

The result is returned invisibly if `plot` is true.

---

**spec.taper***Taper a Time Series by a Cosine Bell*

---

**Description**

Apply a cosine-bell taper to a time series.

**Usage**

```
spec.taper(x, p = 0.1)
```

**Arguments**

- |                |                                                                                                                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | A univariate or multivariate time series                                                                                                                                                                  |
| <code>p</code> | The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series.. |

**Details**

The cosine-bell taper is applied to the first and last `p[i]` observations of time series `x[, i]`.

**Value**

A new time series object.

**See Also**

[spec.pgram](#), [cpgram](#)

**spectrum***Spectral Density Estimation*

## Description

The **spectrum** function estimates the spectral density of a time series.

## Usage

```
spectrum(x, ..., method = c("pgram", "ar"))
```

## Arguments

- |                     |                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | A univariate or multivariate time series.                                                                               |
| <code>method</code> | String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar". |
| <code>...</code>    | Further arguments to specific spec methods or <code>plot.spec</code> .                                                  |

## Details

**spectrum** is a wrapper function which calls the methods `spec.pgram` and `spec.ar`.

The spectrum here is defined with scaling  $1/\text{frequency}(x)$ , following S-PLUS. This makes the spectral density a density over the range  $(-\text{frequency}(x)/2, +\text{frequency}(x)/2]$ , whereas a more common scaling is  $2\pi$  and range  $(-0.5, 0.5]$  (e.g., Bloomfield) or 1 and range  $(-\pi, \pi]$ .

If available, a confidence interval will be plotted by `plot.spec`: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

## Value

An object of class "spec", which is a list containing at least the following components:

- |                     |                                                                                                                                                                                                                                                                                          |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>freq</code>   | vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see 'Details' below.                                                               |
| <code>spec</code>   | Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to <code>freq</code> .                                                                                                                              |
| <code>coh</code>    | NULL for univariate series. For multivariate time series, a matrix containing the <i>squared</i> coherency between different series. Column $i + (j - 1) * (j - 2)/2$ of <code>coh</code> contains the squared coherency between columns $i$ and $j$ of <code>x</code> , where $i < j$ . |
| <code>phase</code>  | NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as <code>coh</code> .                                                                                                             |
| <code>series</code> | The name of the time series.                                                                                                                                                                                                                                                             |
| <code>snames</code> | For multivariate input, the names of the component series.                                                                                                                                                                                                                               |
| <code>method</code> | The method used to calculate the spectrum.                                                                                                                                                                                                                                               |

The result is returned invisibly if `plot` is true.

**Note**

The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

spectrum(lh, method = "ar")
spectrum(ldeaths, method = "ar")
```

**Description**

Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a *function* performing the interpolation.

## Usage

```
splinefun(x, y = NULL,
 method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"),
 ties = mean)

spline(x, y = NULL, n = 3*length(x), method = "fmm",
 xmin = min(x), xmax = max(x), xout, ties = mean)

splinefunH(x, y, m)
```

## Arguments

|                         |                                                                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see <a href="#">xy.coords</a> .<br><code>y</code> must be increasing or decreasing for <code>method = "hyman"</code> . |
| <code>m</code>          | (for <code>splinefunH()</code> ): vector of <i>slopes</i> $m_i$ at the points $(x_i, y_i)$ ; these together determine the <b>Hermite</b> “spline” which is piecewise cubic, (only) <i>once</i> differentiable continuously.                         |
| <code>method</code>     | specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic", "monoH.FC" and "hyman".                                                                                                                                  |
| <code>n</code>          | if <code>xout</code> is left unspecified, interpolation takes place at <code>n</code> equally spaced points spanning the interval $[xmin, xmax]$ .                                                                                                  |
| <code>xmin, xmax</code> | left-hand and right-hand endpoint of the interpolation interval (when <code>xout</code> is unspecified).                                                                                                                                            |
| <code>xout</code>       | an optional set of values specifying where interpolation is to take place.                                                                                                                                                                          |
| <code>ties</code>       | Handling of tied <code>x</code> values. Either a function with a single vector argument returning a single number result or the string "ordered".                                                                                                   |

## Details

The inputs can contain missing values which are deleted, so at least one complete (`x, y`) pair is required. If `method = "fmm"`, the spline used is that of Forsythe, Malcolm and Moler (an exact cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when `method = "natural"`, and periodic splines when `method = "periodic"`.

The method "monoH.FC" computes a *monotone* Hermite spline according to the method of Fritsch and Carlson. It does so by determining slopes such that the Hermite spline, determined by  $(x_i, y_i, m_i)$ , is monotone (increasing or decreasing) **iff** the data are.

Method "hyman" computes a *monotone* cubic spline using Hyman filtering of an `method = "fmm"` fit for strictly monotonic inputs. (Added in R 2.15.2.)

These interpolation splines can also be used for extrapolation, that is prediction at points outside the range of `x`. Extrapolation makes little sense for `method = "fmm"`; for natural splines it is linear using the slope of the interpolating curve at the nearest data point.

## Value

`spline` returns a list containing components `x` and `y` which give the ordinates where interpolation took place and the interpolated values.

`splinefun` returns a function with formal arguments `x` and `deriv`, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (`deriv = 0`), or its derivatives (`deriv`

= 1, 2, 3) at the points  $x$ , where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

### Warning

The value returned by `splinfun` contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer in R  $\geq 3.0.0$ .

### Author(s)

R Core Team.

Simon Wood for the original code for Hyman filtering.

### Examples

```
require(graphics)

op <- par(mfrow = c(2,1), mgp = c(2,.8,0), mar = 0.1+c(3,3,3,1))
n <- 9
x <- 1:n
y <- rnorm(n)
plot(x, y, main = paste("spline[fun](.) through", n, "points"))
lines(spline(x, y))
lines(spline(x, y, n = 201), col = 2)

y <- (x-6)^2
plot(x, y, main = "spline(.) -- 3 methods")
lines(spline(x, y, n = 201), col = 2)
lines(spline(x, y, n = 201, method = "natural"), col = 3)
lines(spline(x, y, n = 201, method = "periodic"), col = 4)
legend(6, 25, c("fmm","natural","periodic"), col = 2:4, lty = 1)

y <- sin((x-0.5)*pi)
```

```

f <- splinefun(x, y)
ls(envir = environment(f))
splinecoef <- get("z", envir = environment(f))
curve(f(x), 1, 10, col = "green", lwd = 1.5)
points(splinecoef, col = "purple", cex = 2)
curve(f(x, deriv = 1), 1, 10, col = 2, lwd = 1.5)
curve(f(x, deriv = 2), 1, 10, col = 2, lwd = 1.5, n = 401)
curve(f(x, deriv = 3), 1, 10, col = 2, lwd = 1.5, n = 401)
par(op)

Manual spline evaluation --- demo the coefficients :
.x <- splinecoef$x
u <- seq(3, 6, by = 0.25)
(ii <- findInterval(u, .x))
dx <- u - .x[ii]
f.u <- with(splinecoef,
 y[ii] + dx*(b[ii] + dx*(c[ii] + dx* d[ii])))
stopifnot(all.equal(f(u), f.u))

An example with ties (non-unique x values):
set.seed(1); x <- round(rnorm(30), 1); y <- sin(pi * x) + rnorm(30)/10
plot(x, y, main = "spline(x,y) when x has ties")
lines(spline(x, y, n = 201), col = 2)
visualizes the non-unique ones:
tx <- table(x); mx <- as.numeric(names(tx[tx > 1]))
ry <- matrix(unlist(tapply(y, match(x, mx), range, simplify = FALSE)),
 ncol = 2, byrow = TRUE)
segments(mx, ry[, 1], mx, ry[, 2], col = "blue", lwd = 2)

An example of monotone interpolation
n <- 20
set.seed(11)
x. <- sort(runif(n)) ; y. <- cumsum(abs(rnorm(n)))
plot(x., y.)
curve(splinefun(x., y.)(x), add = TRUE, col = 2, n = 1001)
curve(splinefun(x., y., method = "monoH.FC")(x), add = TRUE, col = 3, n = 1001)
curve(splinefun(x., y., method = "hyman") (x), add = TRUE, col = 4, n = 1001)
legend("topleft",
 paste0("splinefun(\\"", c("fmm", "monoH.FC", "hyman"), "\")"),
 col = 2:4, lty = 1, bty = "n")

and one from Fritsch and Carlson (1980), Dougherty et al (1989)
x. <- c(7.09, 8.09, 8.19, 8.7, 9.2, 10, 12, 15, 20)
f <- c(0, 2.76429e-5, 4.37498e-2, 0.169183, 0.469428, 0.943740,
 0.998636, 0.999919, 0.999994)
s0 <- splinefun(x., f)
s1 <- splinefun(x., f, method = "monoH.FC")
s2 <- splinefun(x., f, method = "hyman")
plot(x., f, ylim = c(-0.2, 1.2))
curve(s0(x), add = TRUE, col = 2, n = 1001) -> m0
curve(s1(x), add = TRUE, col = 3, n = 1001)
curve(s2(x), add = TRUE, col = 4, n = 1001)
legend("right",
 paste0("splinefun(\\"", c("fmm", "monoH.FC", "hyman"), "\")"),
 col = 2:4, lty = 1, bty = "n")

they seem identical, but are not quite:

```

```

xx <- m0$x
plot(xx, s1(xx) - s2(xx), type = "l", col = 2, lwd = 2,
 main = "Difference monoH.FC - hyman"); abline(h = 0, lty = 3)

x <- xx[xx < 10.2] ## full range: x <- xx .. does not show enough
ccol <- adjustcolor(2:4, 0.8)
matplot(x, cbind(s0(x, deriv = 2), s1(x, deriv = 2), s2(x, deriv = 2))^2,
 lwd = 2, col = ccol, type = "l", ylab = quote({{f*second}(x)}^2),
 main = expression({{f*second}(x)}^2 ~" for the three splines"))
legend("topright",
 paste0("splinefun(\", c(\"fmm\", \"monoH.FC\", \"hyman\"), \"\")"),
 lwd = 2, col = ccol, lty = 1:3, bty = "n")
--> "hyman" has slightly smaller Integral f(x)^2 dx than "FC",
here, and both are much worse than the regular fmm spline.

```

## Description

This `selfStart` model evaluates the asymptotic regression function and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Asym`, `R0`, and `lrc` for a given set of data.

## Usage

```
SSasymp(input, Asym, R0, lrc)
```

## Arguments

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                              |
| <code>Asym</code>  | a numeric parameter representing the horizontal asymptote on the right side (very large values of <code>input</code> ). |
| <code>R0</code>    | a numeric parameter representing the response when <code>input</code> is zero.                                          |
| <code>lrc</code>   | a numeric parameter representing the natural logarithm of the rate constant.                                            |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym + (R0 - Asym) * exp(-exp(lrc) * input)`. If all of the arguments `Asym`, `R0`, and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

## SSasympOff

### *Self-Starting Nls Asymptotic Regression Model with an Offset*

## Description

This `selfStart` model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an `initial` attribute that creates initial estimates of the parameters `Asym`, `lrc`, and `c0`.

## Usage

```
SSasympOff(input, Asym, lrc, c0)
```

## Arguments

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                              |
| <code>Asym</code>  | a numeric parameter representing the horizontal asymptote on the right side (very large values of <code>input</code> ). |
| <code>lrc</code>   | a numeric parameter representing the natural logarithm of the rate constant.                                            |
| <code>c0</code>    | a numeric parameter representing the <code>input</code> for which the response is zero.                                 |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*(input - c0)))`. If all of the arguments `Asym`, `lrc`, and `c0` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSasympOrig

*Self-Starting Nls Asymptotic Regression Model through the Origin*

## Description

This `selfStart` model evaluates the asymptotic regression function through the origin and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Asym` and `lrc` for a given set of data.

## Usage

```
SSasympOrig(input, Asym, lrc)
```

## Arguments

- |                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                   |
| <code>Asym</code>  | a numeric parameter representing the horizontal asymptote.                   |
| <code>lrc</code>   | a numeric parameter representing the natural logarithm of the rate constant. |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*input))`. If all of the arguments `Asym` and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSbiexp

*Self-Starting Nls Biexponential model*

## Description

This `selfStart` model evaluates the biexponential model function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters `A1`, `lrc1`, `A2`, and `lrc2`.

## Usage

```
SSbiexp(input, A1, lrc1, A2, lrc2)
```

## Arguments

|                    |                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                             |
| <code>A1</code>    | a numeric parameter representing the multiplier of the first exponential.                              |
| <code>lrc1</code>  | a numeric parameter representing the natural logarithm of the rate constant of the first exponential.  |
| <code>A2</code>    | a numeric parameter representing the multiplier of the second exponential.                             |
| <code>lrc2</code>  | a numeric parameter representing the natural logarithm of the rate constant of the second exponential. |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `A1*exp(-exp(lrc1)*input)+A2*exp(-exp(lrc2)*input)`. If all of the arguments `A1`, `lrc1`, `A2`, and `lrc2` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSD

*SSD Matrix and Estimated Variance Matrix in Multivariate Models*

## Description

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

## Usage

```
S3 method for class mlm
SSD(object, ...)

S3 methods for class SSD and mlm
estVar(object, ...)
```

## Arguments

|        |                                                        |
|--------|--------------------------------------------------------|
| object | object of class "mlm", or "SSD" in the case of estVar. |
| ...    | Unused                                                 |

## Value

SSD() returns a list of class "SSD" containing the following components

|      |                                                  |
|------|--------------------------------------------------|
| SSD  | The residual sums of squares and products matrix |
| df   | Degrees of freedom                               |
| call | Copied from object                               |

estVar returns a matrix with the estimated variances and covariances.

*Self-Starting Nls First-order Compartment Model*

## Description

This `selfStart` model evaluates the first-order compartment function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters `lKe`, `lKa`, and `lCl`.

## Usage

```
SSfol(Dose, input, lKe, lKa, lCl)
```

## Arguments

|                    |                                                                                          |
|--------------------|------------------------------------------------------------------------------------------|
| <code>Dose</code>  | a numeric value representing the initial dose.                                           |
| <code>input</code> | a numeric vector at which to evaluate the model.                                         |
| <code>lKe</code>   | a numeric parameter representing the natural logarithm of the elimination rate constant. |
| <code>lKa</code>   | a numeric parameter representing the natural logarithm of the absorption rate constant.  |
| <code>lCl</code>   | a numeric parameter representing the natural logarithm of the clearance.                 |

## Value

a numeric vector of the same length as `input`, which is the value of the expression

$$\frac{Dose * \exp(lKe + lKa - lCl) * (\exp(-\exp(lKe)*input) - \exp(-\exp(lKa)*input))}{(\exp(lKa) - \exp(lKe))}$$

If all of the arguments `lKe`, `lKa`, and `lCl` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSfp1

*Self-Starting Nls Four-Parameter Logistic Model*

### Description

This `selfStart` model evaluates the four-parameter logistic function and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `A`, `B`, `xmid`, and `scal` for a given set of data.

### Usage

`SSfp1(input, A, B, xmid, scal)`

### Arguments

|                    |                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                                                                                                                          |
| <code>A</code>     | a numeric parameter representing the horizontal asymptote on the left side (very small values of <code>input</code> ).                                                                                              |
| <code>B</code>     | a numeric parameter representing the horizontal asymptote on the right side (very large values of <code>input</code> ).                                                                                             |
| <code>xmid</code>  | a numeric parameter representing the <code>input</code> value at the inflection point of the curve. The value of <code>SSfp1</code> will be midway between <code>A</code> and <code>B</code> at <code>xmid</code> . |
| <code>scal</code>  | a numeric scale parameter on the <code>input</code> axis.                                                                                                                                                           |

### Value

a numeric vector of the same length as `input`. It is the value of the expression  $A + (B - A) / (1 + \exp((xmid - input) / scal))$ . If all of the arguments `A`, `B`, `xmid`, and `scal` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSgompertz

*Self-Starting Nls Gompertz Growth Model*

**Description**

This selfStart model evaluates the Gompertz growth model and its gradient. It has an **initial** attribute that creates initial estimates of the parameters Asym, b2, and b3.

**Usage**

`SSgompertz(x, Asym, b2, b3)`

**Arguments**

|                   |                                                                     |
|-------------------|---------------------------------------------------------------------|
| <code>x</code>    | a numeric vector of values at which to evaluate the model.          |
| <code>Asym</code> | a numeric parameter representing the asymptote.                     |
| <code>b2</code>   | a numeric parameter related to the value of the function at $x = 0$ |
| <code>b3</code>   | a numeric parameter related to the scale the $x$ axis.              |

**Value**

a numeric vector of the same length as input. It is the value of the expression  $Asym * exp(-b2 * b3^x)$ . If all of the arguments Asym, b2, and b3 are names of objects the gradient matrix with respect to these names is attached as an attribute named **gradient**.

SSlogis

*Self-Starting Nls Logistic Model*

## Description

This `selfStart` model evaluates the logistic function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters `Asym`, `xmid`, and `scal`.

## Usage

```
SSlogis(input, Asym, xmid, scal)
```

## Arguments

|                    |                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                                                                                              |
| <code>Asym</code>  | a numeric parameter representing the asymptote.                                                                                                                                         |
| <code>xmid</code>  | a numeric parameter representing the <code>x</code> value at the inflection point of the curve.<br>The value of <code>SSlogis</code> will be <code>Asym/2</code> at <code>xmid</code> . |
| <code>scal</code>  | a numeric scale parameter on the <code>input</code> axis.                                                                                                                               |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym/(1+exp((xmid-input)/scal))`. If all of the arguments `Asym`, `xmid`, and `scal` are names of objects the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSmicmen

*Self-Starting Nls Michaelis-Menten Model*

## Description

This `selfStart` model evaluates the Michaelis-Menten model and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters  $V_m$  and  $K$ .

## Usage

```
SSmicmen(input, Vm, K)
```

## Arguments

|                    |                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                                                                                            |
| <code>Vm</code>    | a numeric parameter representing the maximum value of the response.                                                                                                                   |
| <code>K</code>     | a numeric parameter representing the <code>input</code> value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter. |

## Value

a numeric vector of the same length as `input`. It is the value of the expression  $V_m * input / (K + input)$ . If both the arguments `Vm` and `K` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

## Description

This `selfStart` model evaluates the Weibull model for growth curve data and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Asym`, `Drop`, `lrc`, and `pwr` for a given set of data.

## Usage

```
SSweibull(x, Asym, Drop, lrc, pwr)
```

## Arguments

|                   |                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | a numeric vector of values at which to evaluate the model.                                                          |
| <code>Asym</code> | a numeric parameter representing the horizontal asymptote on the right side (very small values of <code>x</code> ). |
| <code>Drop</code> | a numeric parameter representing the change from <code>Asym</code> to the y intercept.                              |
| <code>lrc</code>  | a numeric parameter representing the natural logarithm of the rate constant.                                        |
| <code>pwr</code>  | a numeric parameter representing the power to which <code>x</code> is raised.                                       |

## Details

This model is a generalization of the `SSasymp` model in that it reduces to `SSasymp` when `pwr` is unity.

## Value

a numeric vector of the same length as `x`. It is the value of the expression `Asym-Drop*exp(-exp(lrc)*x^pwr)`. If all of the arguments `Asym`, `Drop`, `lrc`, and `pwr` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

summary(fm1)
```

start

*Encode the Terminal Times of Time Series*

## Description

Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.

## Usage

```
start(x, ...)
end(x, ...)
```

## Arguments

|     |                                                                  |
|-----|------------------------------------------------------------------|
| x   | a univariate or multivariate time-series, or a vector or matrix. |
| ... | extra arguments for future methods.                              |

## Details

These are generic functions, which will use the [tsp](#) attribute of x if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as `c(1995, 7)`. For a series of frequency f, time  $n+i/f$  is presented as `c(n, i+1)` (even for  $i = 0$  and  $f = 1$ ).

## Warning

The representation used by `start` and `end` has no meaning unless the frequency is supplied.

**stat.anova***GLM Anova Statistics*

## Description

This is a utility function, used in `lm` and `glm` methods for `anova(..., test != NULL)` and should not be used by the average user.

## Usage

```
stat.anova(table, test = c("Rao", "LRT", "Chisq", "F", "Cp"),
 scale, df.scale, n)
```

## Arguments

|                       |                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------|
| <code>table</code>    | numeric matrix as results from <code>anova.glm(..., test = NULL)</code> .                  |
| <code>test</code>     | a character string, matching one of "Rao", "LRT", "Chisq", "F" or "Cp".                    |
| <code>scale</code>    | a residual mean square or other scale estimate to be used as the denominator in an F test. |
| <code>df.scale</code> | degrees of freedom corresponding to <code>scale</code> .                                   |
| <code>n</code>        | number of observations.                                                                    |

## Value

A matrix which is the original `table`, augmented by a column of test statistics, depending on the `test` argument.

## Examples

```
##-- Continued from ?glm:
print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
 scale = sum(resid(glm.D93, "pearson")^2)/4,
 df.scale = 4, n = 9)
```

**stats-deprecated**      *Deprecated Functions in Package stats*

---

### Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as the next release.

### Usage

```
plclust(tree, hang = 0.1, unit = FALSE, level = FALSE, hmin = 0,
 square = TRUE, labels = NULL, plot. = TRUE,
 axes = TRUE, frame.plot = FALSE, ann = TRUE,
 main = "", sub = NULL, xlab = NULL, ylab = "Height")
```

### Arguments

|                                    |                                                                                                                                                                                              |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tree</code>                  | an object of the type produced by <a href="#">hclust</a> .                                                                                                                                   |
| <code>hang</code>                  | The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.                                          |
| <code>unit</code>                  | logical. If true, the splits are plotted at equally-spaced heights rather than at the height in the object.                                                                                  |
| <code>labels</code>                | A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If <code>labels</code> = FALSE no labels at all are plotted. |
| <code>axes, frame.plot, ann</code> | logical flags as in <a href="#">plot.default</a> .                                                                                                                                           |
| <code>main, sub, xlab, ylab</code> | character strings for <a href="#">title</a> . <code>sub</code> and <code>xlab</code> have a non-NULL default when there's a <code>tree\$call</code> .                                        |
| <code>...</code>                   | Further graphical arguments. E.g. <code>cex</code> controls the size of the labels (if plotted) in the same way as <a href="#">text</a> .                                                    |
| <code>hmin</code>                  | numeric. All heights less than <code>hmin</code> are regarded as being <code>hmin</code> : this can be used to suppress detail at the bottom of the tree.                                    |
| <code>level, square, plot.</code>  | unimplemented arguments for S-PLUS compatibility.                                                                                                                                            |

### Details

`plclust` is a deprecated wrapper for the `plot` method for [hclust](#), provided long ago for S-PLUS compatibility.

step*Choose a model by AIC in a Stepwise Algorithm*

---

## Description

Select a formula-based model by AIC.

## Usage

```
step(object, scope, scale = 0,
 direction = c("both", "backward", "forward"),
 trace = 1, keep = NULL, steps = 1000, k = 2, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | an object representing a model of an appropriate class (mainly " <code>lm</code> " and " <code>glm</code> "). This is used as the initial model in the stepwise search.                                                                                                |
| scope     | defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components <code>upper</code> and <code>lower</code> , both formulae. See the details for how to specify the formulae and how they are used. |
| scale     | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>aov</code> and <code>glm</code> models. The default value, 0, indicates the scale should be estimated: see <a href="#">extractAIC</a> .               |
| direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the <code>scope</code> argument is missing the default for <code>direction</code> is "backward".                                                             |
| trace     | if positive, information is printed during the running of <code>step</code> . Larger values may give more detailed information.                                                                                                                                        |
| keep      | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically <code>keep</code> will select a subset of the components of the object and return them. The default is not to keep anything.         |
| steps     | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.                                                                                                                   |
| k         | the multiple of the number of degrees of freedom used for the penalty. Only <code>k = 2</code> gives the genuine AIC: <code>k = log(n)</code> is sometimes referred to as BIC or SBC.                                                                                  |
| ...       | any additional arguments to <a href="#">extractAIC</a> .                                                                                                                                                                                                               |

## Details

`step` uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for [extractAIC](#). When the additive constant can be chosen so that AIC is equal to Mallows'  $C_p$ , this is done and the tables are labelled appropriately.

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the `upper` component. If `scope` is a single formula, it specifies the `upper` component, and the `lower` model is empty. If `scope` is missing, the initial model is used as the `upper` model.

Models specified by scope can be templates to update object as used by [update.formula](#). So using . in a scope formula means ‘what is already there’, with .^2 indicating all interactions of existing terms.

There is a potential problem in using [glm](#) fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The “glm” method for function [extractAIC](#) makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

### Value

the stepwise-selected model is returned, with up to two additional components. There is an “anova” component corresponding to the steps taken in the search, as well as a “keep” component if the keep= argument was supplied in the call. The “Resid. Dev” column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding [lm](#), [aov](#) and [survreg](#) fits, for example).

### Warning

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R’s default of na.action = na.omit is used. We suggest you remove the missing values first.

Calls to the function [nobs](#) are used to check that the number of observations involved in the fitting process remains unchanged.

### Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use [stepAIC](#) in package **MASS** for a wider range of object classes.

### Author(s)

B. D. Ripley: `step` is a slightly simplified version of [stepAIC](#) in package **MASS** (Venables & Ripley, 2002 and earlier editions).

The idea of a `step` function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

slm1 <- step(lm1)
summary(slm1)
slm1$anova
```

stepfun

*Step Function Class*

## Description

Given the vectors  $(x_1, \dots, x_n)$  and  $(y_0, y_1, \dots, y_n)$  (one value more!), `stepfun(x, y, ...)` returns an interpolating ‘step’ function, say `fn`. I.e.,  $fn(t) = c_i$  (constant) for  $t \in (x_i, x_{i+1})$  and at the abscissa values, if (by default) `right = FALSE`,  $fn(x_i) = y_i$  and for `right = TRUE`,  $fn(x_i) = y_{i-1}$ , for  $i = 1, \dots, n$ .

The value of the constant  $c_i$  above depends on the ‘continuity’ parameter `f`. For the default, `right = FALSE`,  $f = 0$ , `fn` is a *cadlag* function, i.e., continuous at right, limit (‘the point’) at left. In general,  $c_i$  is interpolated in between the neighbouring  $y$  values,  $c_i = (1 - f)y_i + f \cdot y_{i+1}$ . Therefore, for non-0 values of `f`, `fn` may no longer be a proper step function, since it can be discontinuous from both sides, unless `right = TRUE`,  $f = 1$  which is right-continuous.

## Usage

```
stepfun(x, y, f = as.numeric(right), ties = "ordered",
 right = FALSE)

is.stepfun(x)
knots(Fn, ...)
as.stepfun(x, ...)

S3 method for class stepfun
print(x, digits = getOption("digits") - 2, ...)

S3 method for class stepfun
summary(object, ...)
```

## Arguments

- `x` numeric vector giving the knots or jump locations of the step function for `stepfun()`. For the other functions, `x` is as object below.
- `y` numeric vector one longer than `x`, giving the heights of the function values *between* the `x` values.
- `f` a number between 0 and 1, indicating how interpolation outside the given `x` values should happen. See [approxfun](#).
- `ties` Handling of tied `x` values. Either a function or the string “`ordered`”. See [approxfun](#).

|            |                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------|
| right      | logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa. |
| Fn, object | an R object inheriting from "stepfun".                                                                   |
| digits     | number of significant digits to use, see <a href="#">print</a> .                                         |
| ...        | potentially further arguments (required by the generic).                                                 |

**Value**

A function of class "stepfun", say fn.

There are methods available for summarizing ("summary(.)"), representing ("print(.)") and plotting ("plot(.)", see [plot.stepfun](#)) "stepfun" objects.

The [environment](#) of fn contains all the information needed;

|                   |                                                             |
|-------------------|-------------------------------------------------------------|
| "x", "y"          | the original arguments                                      |
| "n"               | number of knots (x values)                                  |
| "f"               | continuity parameter                                        |
| "yleft", "yright" | the function values <i>outside</i> the knots                |
| "method"          | (always == "constant", from <a href="#">approxfun</a> (.)). |

The knots are also available via [knots](#)(fn).

**Author(s)**

Martin Maechler, <[maechler@stat.math.ethz.ch](mailto:maechler@stat.math.ethz.ch)> with some basic code from Thomas Lumley.

**See Also**

[approxfun](#) and [splinefun](#).

**Examples**

```
y0 <- c(1., 2., 4., 3.)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = 0.2)
sfun1 <- stepfun(1:3, y0, f = 1)
sfun1c <- stepfun(1:3, y0, right = TRUE) # hence f=1
sfun0
summary(sfun0)
summary(sfun.2)

look at the internal structure:
unclass(sfun0)
ls(envir = environment(sfun0))

x0 <- seq(0.5, 3.5, by = 0.25)
rbind(x = x0, f.f0 = sfun0(x0), f.f02 = sfun.2(x0),
 f.f1 = sfun1(x0), f.f1c = sfun1c(x0))
Identities :
stopifnot(identical(y0[-1], sfun0(1:3)), # right = FALSE
 identical(y0[-4], sfun1c(1:3))) # right = TRUE
```

---

stl*Seasonal Decomposition of Time Series by Loess*

---

## Description

Decompose a time series into seasonal, trend and irregular components using loess, acronym STL.

## Usage

```
stl(x, s.window, s.degree = 0,
 t.window = NULL, t.degree = 1,
 l.window = nextodd(period), l.degree = t.degree,
 s.jump = ceiling(s.window/10),
 t.jump = ceiling(t.window/10),
 l.jump = ceiling(l.window/10),
 robust = FALSE,
 inner = if(robust) 1 else 2,
 outer = if(robust) 15 else 0,
 na.action = na.fail)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                      | univariate time series to be decomposed. This should be an object of class "ts" with a frequency greater than one.                                                                                                                                                                                                                      |
| s.window               | either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd. This has no default.                                                                                                                                                                                     |
| s.degree               | degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.                                                                                                                                                                                                                                                      |
| t.window               | the span (in lags) of the loess window for trend extraction, which should be odd. If NULL, the default, nextodd(ceiling((1.5*period) / (1-(1.5/s.window)))), is taken.                                                                                                                                                                  |
| t.degree               | degree of locally-fitted polynomial in trend extraction. Should be zero or one.                                                                                                                                                                                                                                                         |
| l.window               | the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to frequency(x) which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one. |
| l.degree               | degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.                                                                                                                                                                                                                                                  |
| s.jump, t.jump, l.jump | integers at least one to increase speed of the respective smoother. Linear interpolation happens between every *.jumpth value.                                                                                                                                                                                                          |
| robust                 | logical indicating if robust fitting be used in the loess procedure.                                                                                                                                                                                                                                                                    |
| inner                  | integer; the number of 'inner' (backfitting) iterations; usually very few (2) iterations suffice.                                                                                                                                                                                                                                       |
| outer                  | integer; the number of 'outer' robustness iterations.                                                                                                                                                                                                                                                                                   |
| na.action              | action on missing values.                                                                                                                                                                                                                                                                                                               |

## Details

The seasonal component is found by *loess* smoothing the seasonal sub-series (the series of all January values, ...); if `s.window = "periodic"` smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The remainder component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "stl" objects, see, [plot.stl](#).

## Value

`stl` returns an object of class "stl" with components

|                          |                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>time.series</code> | a multiple time series with columns <code>seasonal</code> , <code>trend</code> and <code>remainder</code> . |
| <code>weights</code>     | the final robust weights (all one if fitting is not done robustly).                                         |
| <code>call</code>        | the matched call.                                                                                           |
| <code>win</code>         | integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers.                          |
| <code>deg</code>         | integer (length 3) vector with the polynomial degrees for these smoothers.                                  |
| <code>jump</code>        | integer (length 3) vector with the 'jumps' (skips) used for these smoothers.                                |
| <code>ni</code>          | number of <code>inner</code> iterations                                                                     |
| <code>no</code>          | number of <code>outer</code> robustness iterations                                                          |

## Note

This is similar to but not identical to the `stl` function in S-PLUS. The `remainder` component given by S-PLUS is the sum of the `trend` and `remainder` series from this function.

## Author(s)

B.D. Ripley; Fortran code by Cleveland *et al.* (1990) from 'netlib'.

## References

R. B. Cleveland, W. S. Cleveland, J.E. McRae, and I. Terpenning (1990) STL: A Seasonal-Trend Decomposition Procedure Based on Loess. *Journal of Official Statistics*, **6**, 3–73.

## See Also

[plot.stl](#) for `stl` methods; [loess](#) in package `stats` (which is not actually used in `stl`).  
[StructTS](#) for different kind of decomposition.

## Examples

```
require(graphics)

plot(stl(nottem, "per"))
plot(stl(nottem, s.window = 4, t.window = 50, t.jump = 1))

plot(stllc <- stl(log(co2), s.window = 21))
summary(stllc)
linear trend, strict period.
plot(stl(log(co2), s.window = "per", t.window = 1000))
```

```

Two STL plotted side by side :
 stmd <- stl(mdeaths, s.window = "per") # non-robust
summary(stmR <- stl(mdeaths, s.window = "per", robust = TRUE))
op <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0), mfcol = c(4, 2))
plot(stmd, set.pars = NULL, labels = NULL,
 main = "stl(mdeaths, s.w = \"per\")", robust = FALSE / TRUE)
plot(stmR, set.pars = NULL)
mark the outliers :
(i0 <- which(stmR $ weights < 1e-8)) # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[i0], 0.8* sts[,"remainder"][[i0]], pch = 4, col = "red")
par(op) # reset

```

## Description

Methods for objects of class **stl**, typically the result of **stl**. The plot method does a multiple figure plot with some flexibility.

There are also (non-visible) print and summary methods.

## Usage

```

S3 method for class stl
plot(x, labels = colnames(X),
 set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
 tck = -0.01, mfrow = c(nplot, 1)),
 main = NULL, range.bars = TRUE, ...,
 col.range = "light gray")

```

## Arguments

|                   |                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>x</b>          | <b>stl</b> object.                                                                                                  |
| <b>labels</b>     | character of length 4 giving the names of the component time-series.                                                |
| <b>set.pars</b>   | settings for <b>par(.)</b> when setting up the plot.                                                                |
| <b>main</b>       | plot main title.                                                                                                    |
| <b>range.bars</b> | logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates. |
| <b>...</b>        | further arguments passed to or from other methods.                                                                  |
| <b>col.range</b>  | colour to be used for the range bars, if plotted. Note this appears after <b>...</b> and so cannot be abbreviated.  |

StructTS*Fit Structural Time Series*

---

**Description**

Fit a structural model for a time series by maximum likelihood.

**Usage**

```
StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
 fixed = NULL, optim.control = NULL)
```

**Arguments**

- |                            |                                                                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a univariate numeric time series. Missing values are allowed.                                                                                                                                        |
| <code>type</code>          | the class of structural model. If omitted, a BSM is used for a time series with <code>frequency(x) &gt; 1</code> , and a local trend model otherwise.                                                |
| <code>init</code>          | initial values of the variance parameters.                                                                                                                                                           |
| <code>fixed</code>         | optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in <code>fixed</code> will be varied. Probably most useful for setting variances to zero. |
| <code>optim.control</code> | List of control parameters for <code>optim</code> . Method "L-BFGS-B" is used.                                                                                                                       |

**Details**

*Structural time series* models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the *local level* model specified by `type = "level"`. This has an underlying level  $\mu_t$  which evolves by

$$\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

The observations are

$$x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

There are two parameters,  $\sigma_\xi^2$  and  $\sigma_\epsilon^2$ . It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The *local linear trend model*, `type = "trend"`, has the same measurement equation, but with a time-varying slope in the dynamics for  $\mu_t$ , given by

$$\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

$$\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)$$

with three variance parameters. It is not uncommon to find  $\sigma_\zeta^2 = 0$  (which reduces to the local level model) or  $\sigma_\xi^2 = 0$ , which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The *basic structural model*, `type = "BSM"`, is a local trend model with an additional seasonal component. Thus the measurement equation is

$$x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

where  $\gamma_t$  is a seasonal component with dynamics

$$\gamma_{t+1} = -\gamma_t + \cdots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma_\omega^2)$$

The boundary case  $\sigma_\omega^2 = 0$  corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

### Value

A list of class "StructTS" with components:

|                                          |                                                                                                                                                                                                                                   |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>coef</code>                        | the estimated variances of the components.                                                                                                                                                                                        |
| <code>loglik</code>                      | the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to <a href="#">arima</a> nor different types of structural models. |
| <code>loglik0</code>                     | the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.                                                                                                                                |
| <code>data</code>                        | the time series <code>x</code> .                                                                                                                                                                                                  |
| <code>residuals</code>                   | the standardized residuals.                                                                                                                                                                                                       |
| <code>fitted</code>                      | a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).                                                       |
| <code>call</code>                        | the matched call.                                                                                                                                                                                                                 |
| <code>series</code>                      | the name of the series <code>x</code> .                                                                                                                                                                                           |
| <code>code</code>                        | the convergence code returned by <a href="#">optim</a> .                                                                                                                                                                          |
| <code>model</code> , <code>model0</code> | Lists representing the Kalman Filter used in the fitting. See <a href="#">KalmanLike</a> . <code>model0</code> is the initial state of the filter, <code>model</code> its final state.                                            |
| <code>xtsp</code>                        | the <code>tsp</code> attributes of <code>x</code> .                                                                                                                                                                               |

### Note

Optimization of structural models is a lot harder than many of the references admit. For example, the [AirPassengers](#) data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by StructTS. It is quite common to find fits with one or more variances zero, and this can include  $\sigma_\epsilon^2$ .

require(graphics)

trees <- window(treering, start = 0)
(fit <- StructTS(trees, type = "level"))
plot(trees)
lines(fitted(fit), col = "green")
tsdiag(fit)

(fit <- StructTS(log10(UKgas), type = "BSM"))
par(mfrow = c(4, 1)) # to give appropriate aspect ratio for next plot.
plot(log10(UKgas))
plot(cbind(fitted(fit), resid(resid(fit))), main = "UK gas consumption")

keep some parameters fixed; trace optimizer:
StructTS(log10(UKgas), type = "BSM", fixed = c(0.1, 0.001, NA, NA),
 optim.control = list(trace = TRUE))

```

**summary.aov**

*Summarize an Analysis of Variance Model*

## Description

Summarize an analysis of variance model.

## Usage

```

S3 method for class aov
summary(object, intercept = FALSE, split,
 expand.split = TRUE, keep.zero.df = TRUE, ...)

S3 method for class aovlist
summary(object, ...)

```

## Arguments

- |                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>object</b><br><b>intercept</b><br><b>split</b><br><b>expand.split</b><br><b>keep.zero.df</b><br><b>...</b> | An object of class "aov" or "aovlist".<br>logical: should intercept terms be included?<br>an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed.<br>logical: should the split apply also to interactions involving the factor?<br>logical: should terms with no degrees of freedom be included?<br>Arguments to be passed to or from other methods, for <code>summary.aovlist</code> including those for <code>summary.aov</code> . |
|---------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Value

An object of class c("summary.aov", "listof") or "summary.aovlist" respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

### Note

The use of `expand.split = TRUE` is little tested: it is always possible to set it to FALSE and specify exactly all the splits required.

### See Also

[aov](#), [summary](#), [model.tables](#), [TukeyHSD](#)

### Examples

```
For a simple example see example(aov)

Cochran and Cox (1957, p.164)
3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
 y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
 P = ordered(gl(3, 3)), N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC, weights = rep(12, 9))
summary(CC.aov)

Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
 P = list(L = 1, Q = 2)))

Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
 expand.split = FALSE)
```

### Description

These functions are all [methods](#) for class `glm` or `summary.glm` objects.

## Usage

```
S3 method for class glm
summary(object, dispersion = NULL, correlation = FALSE,
 symbolic.cor = FALSE, ...)

S3 method for class summary.glm
print(x, digits = max(3, getOption("digits") - 3),
 symbolic.cor = x$symbolic.cor,
 signif.stars = getOption("show.signif.stars"), ...)
```

## Arguments

|                           |                                                                                                                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | an object of class "glm", usually, a result of a call to <a href="#">glm</a> .                                                                                                  |
| <code>x</code>            | an object of class "summary.glm", usually, a result of a call to <a href="#">summary.glm</a> .                                                                                  |
| <code>dispersion</code>   | the dispersion parameter for the family used. Either a single numerical value or <code>NULL</code> (the default), when it is inferred from <code>object</code> (see 'Details'). |
| <code>correlation</code>  | logical; if <code>TRUE</code> , the correlation matrix of the estimated parameters is returned and printed.                                                                     |
| <code>digits</code>       | the number of significant digits to use when printing.                                                                                                                          |
| <code>symbolic.cor</code> | logical. If <code>TRUE</code> , print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers.                                                 |
| <code>signif.stars</code> | logical. If <code>TRUE</code> , 'significance stars' are printed for each coefficient.                                                                                          |
| <code>...</code>          | further arguments passed to or from other methods.                                                                                                                              |

## Details

`print.summary.glm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is `TRUE`. The `coefficients` component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled `t ratio` if the dispersion is estimated, and `z ratio` if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the `t` or `z` ratio based on a Student `t` or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is `NaN`.)

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If `dispersion` is not supplied or `NULL`, the dispersion is taken as 1 for the binomial and Poisson families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

`summary` can be used with Gaussian `glm` fits to handle the case of a linear regression with known error variance, something not handled by [summary.lm](#).

## Value

`summary.glm` returns an object of class "summary.glm", a list with components

|                   |                                          |
|-------------------|------------------------------------------|
| <code>call</code> | the component from <code>object</code> . |
|-------------------|------------------------------------------|

|                |                                                                                                                                          |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| family         | the component from object.                                                                                                               |
| deviance       | the component from object.                                                                                                               |
| contrasts      | the component from object.                                                                                                               |
| df.residual    | the component from object.                                                                                                               |
| null.deviance  | the component from object.                                                                                                               |
| df.null        | the component from object.                                                                                                               |
| deviance.resid | the deviance residuals: see <a href="#">residuals.glm</a> .                                                                              |
| coefficients   | the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.                                    |
| aliased        | named logical vector showing if the original coefficients are aliased.                                                                   |
| dispersion     | either the supplied argument or the inferred/estimated dispersion if the latter is NULL.                                                 |
| df             | a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of coefficients (including aliased ones). |
| cov.unscaled   | the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.                                                 |
| cov.scaled     | ditto, scaled by dispersion.                                                                                                             |
| correlation    | (only if correlation is true.) The estimated correlations of the estimated coefficients.                                                 |
| symbolic.cor   | (only if correlation is true.) The value of the argument symbolic.cor.                                                                   |

summary.lm

*Summarizing Linear Model Fits*

## Description

summary method for class "lm".

## Usage

```
S3 method for class lm
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

S3 method for class summary.lm
print(x, digits = max(3, getOption("digits") - 3),
 symbolic.cor = x$symbolic.cor,
 signif.stars = getOption("show.signif.stars"), ...)
```

## Arguments

|              |                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------|
| object       | an object of class "lm", usually, a result of a call to <a href="#">lm</a> .                                      |
| x            | an object of class "summary.lm", usually, a result of a call to <a href="#">summary.lm</a> .                      |
| correlation  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                     |
| digits       | the number of significant digits to use when printing.                                                            |
| symbolic.cor | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers. |
| signif.stars | logical. If TRUE, 'significance stars' are printed for each coefficient.                                          |
| ...          | further arguments passed to or from other methods.                                                                |

## Details

`print.summary.lm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

## Value

The function `summary.lm` computes and returns a list of summary statistics of the fitted linear model given in `object`, using the components (list elements) "call" and "terms" from its argument, plus

|              |                                                                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| residuals    | the <i>weighted</i> residuals, the usual residuals rescaled by the square root of the weights specified in the call to <code>lm</code> .                                   |
| coefficients | a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted. |
| aliased      | named logical vector showing if the original coefficients are aliased.                                                                                                     |
| sigma        | the square root of the estimated variance of the random error                                                                                                              |

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i w_i R_i^2,$$

where  $R_i$  is the  $i$ -th residual, `residuals[i]`.

`df` degrees of freedom, a 3-vector ( $p, n - p, p*$ ), the first being the number of non-aliased coefficients, the last being the total number of coefficients.

`fstatistic` (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.

`r.squared`  $R^2$ , the 'fraction of variance explained by the model',

$$R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - y^*)^2},$$

where  $y^*$  is the mean of  $y_i$  if there is an intercept and zero otherwise.

`adj.r.squared` the above  $R^2$  statistic 'adjusted', penalizing for higher  $p$ .

`cov.unscaled` a  $p \times p$  matrix of (unscaled) covariances of the  $\hat{\beta}_j, j = 1, \dots, p$ .

`correlation` the correlation matrix corresponding to the above `cov.unscaled`, if `correlation = TRUE` is specified.

`symbolic.cor` (only if `correlation` is true.) The value of the argument `symbolic.cor`.

`na.action` from `object`, if present there.

A summary method for class "manova".

## Usage

```
S3 method for class manova
summary(object,
 test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
 intercept = FALSE, tol = 1e-7, ...)
```

## Arguments

|           |                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------|
| object    | An object of class "manova" or an aov object with multiple responses.                               |
| test      | The name of the test statistic to be used. Partial matching is used so the name can be abbreviated. |
| intercept | logical. If TRUE, the intercept term is included in the table.                                      |
| tol       | tolerance to be used in deciding if the residuals are rank-deficient: see <a href="#">qr</a> .      |
| ...       | further arguments passed to or from other methods.                                                  |

## Details

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks' statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and

Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance `tol` is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

### Value

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

|                                                                                                                                               |                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| <code>row.names</code>                                                                                                                        | The names of the terms, the row names of the <code>stats</code> table if present. |
| <code>SS</code>                                                                                                                               | A named list of sums of squares and product matrices.                             |
| <code>Eigenvalues</code>                                                                                                                      | A matrix of eigenvalues.                                                          |
| <code>stats</code>                                                                                                                            | A matrix of the statistics, approximate F value, degrees of freedom and P value.  |
| otherwise components <code>row.names</code> , <code>SS</code> and <code>Df</code> (degrees of freedom) for the terms (and not the residuals). |                                                                                   |

**Description**

summary method for class "nls".

**Usage**

```
S3 method for class nls
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

S3 method for class summary.nls
print(x, digits = max(3,getOption("digits") - 3),
 symbolic.cor = x$symbolic.cor,
 signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

|              |                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------|
| object       | an object of class "nls".                                                                                      |
| x            | an object of class "summary.nls", usually the result of a call to <code>summary.nls</code> .                   |
| correlation  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                  |
| digits       | the number of significant digits to use when printing.                                                         |
| symbolic.cor | logical. If TRUE, print the correlations in a symbolic form (see <code>symnum</code> ) rather than as numbers. |
| signif.stars | logical. If TRUE, 'significance stars' are printed for each coefficient.                                       |
| ...          | further arguments passed to or from other methods.                                                             |

**Details**

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

`print.summary.nls` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

**Value**

The function `summary.nls` computes and returns a list of summary statistics of the fitted model given in `object`, using the component "formula" from its argument, plus

|              |                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| residuals    | the <i>weighted</i> residuals, the usual residuals rescaled by the square root of the weights specified in the call to <code>nls</code> . |
| coefficients | a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.  |

|                     |                                                                                                                                                                                   |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>sigma</b>        | the square root of the estimated variance of the random error                                                                                                                     |
|                     | $\hat{\sigma}^2 = \frac{1}{n-p} \sum_i R_i^2,$                                                                                                                                    |
|                     | where $R_i$ is the $i$ -th weighted residual.                                                                                                                                     |
| <b>df</b>           | degrees of freedom, a 2-vector $(p, n - p)$ . (Here and elsewhere $n$ omits observations with zero weights.)                                                                      |
| <b>cov.unscaled</b> | a $p \times p$ matrix of (unscaled) covariances of the parameter estimates.                                                                                                       |
| <b>correlation</b>  | the correlation matrix corresponding to the above <b>cov.unscaled</b> , if <b>correlation</b> = TRUE is specified and there are a non-zero number of residual degrees of freedom. |
| <b>symbolic.cor</b> | (only if <b>correlation</b> is true.) The value of the argument <b>symbolic.cor</b> .                                                                                             |

summary(object, loadings = FALSE, cutoff = 0.1, ...)

S3 method for class summary.princomp
print(x, digits = 3, loadings = x$print.loadings,
 cutoff = x$cutoff, ...)
```

## Arguments

|                 |                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------|
| <b>object</b>   | an object of class "princomp", as from <b>princomp()</b> .                              |
| <b>loadings</b> | logical. Should loadings be included?                                                   |
| <b>cutoff</b>   | numeric. Loadings below this cutoff in absolute value are shown as blank in the output. |
| <b>x</b>        | an object of class "summary.princomp".                                                  |
| <b>digits</b>   | the number of significant digits to be used in listing loadings.                        |
| <b>...</b>      | arguments to be passed to or from other methods.                                        |

## Value

**object** with additional components **cutoff** and **print.loadings**.

**See Also**

[princomp](#)

**Examples**

```
summary(pc.cr <- princomp(USArrests, cor = TRUE))
print(summary(princomp(USArrests, cor = TRUE),
 loadings = TRUE, cutoff = 0.2), digits = 2)
```

supsmu

*Friedman's SuperSmoothen*

**Description**

Smooth the (x, y) values by Friedman's 'super smoother'.

**Usage**

```
supsmu(x, y, wt, span = "cv", periodic = FALSE, bass = 0)
```

**Arguments**

|          |                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------|
| x        | x values for smoothing                                                                                                                |
| y        | y values for smoothing                                                                                                                |
| wt       | case weights, by default all equal                                                                                                    |
| span     | the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation. |
| periodic | if TRUE, the x values are assumed to be in [0, 1] and of period 1.                                                                    |
| bass     | controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.                                       |

**Details**

supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with  $k/2$  data points each side of the predicted point, and values of  $k$  as  $0.5 * n$ ,  $0.2 * n$  and  $0.05 * n$ , where  $n$  is the number of data points. If span is specified, a single smoother with span  $span * n$  is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: "For small samples ( $n < 40$ ) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother ( $span > 0$ ) should be used. Reasonable span values are 0.2 to 0.4."

Cases with non-finite values of x, y or wt are dropped, with a warning.

**Value**

A list with components

|   |                                                               |
|---|---------------------------------------------------------------|
| x | the input values in increasing order with duplicates removed. |
| y | the corresponding y values on the fitted curve.               |

 plot(speed, dist)
 lines(supsmu(speed, dist))
 lines(supsmu(speed, dist, bass = 7), lty = 2)
})
```

symnum

*Symbolic Number Coding*

## Description

Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

## Usage

```
symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
 symbols = if(numeric.x) c(" ", ".", ",", "+", "*", "B")
 else c(".", "|"),
 legend = length(symbols) >= 3,
 na = "?", eps = 1e-5, numeric.x = is.numeric(x),
 corr = missing(cutpoints) && numeric.x,
 show.max = if(corr) "1", show.min = NULL,
 abbr.colnames = has.colnames,
 lower.triangular = corr && is.numeric(x) && is.matrix(x),
 diag.lower.tri = corr && !is.null(show.max))
```

## Arguments

- |           |                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | numeric or logical vector or array.                                                                                                                                                                                                                                                                                                             |
| cutpoints | numeric vector whose values $\text{cutpoints}[j] = c_j$ (after augmentation, see corr below) are used for intervals.                                                                                                                                                                                                                            |
| symbols   | character vector, one shorter than (the <i>augmented</i> , see corr below) cutpoints. $\text{symbols}[j] = s_j$ are used as 'code' for the (half open) interval $(c_j, c_{j+1}]$ . When <code>numeric.x</code> is FALSE, i.e., by default when argument <code>x</code> is logical, the default is <code>c(".", " ")</code> (graphical 0 / 1 s). |

|                  |                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| legend           | logical indicating if a "legend" attribute is desired.                                                                                                                                                                                                                                                                                                                       |
| na               | character or logical. How NAs are coded. If na == FALSE, NAs are coded invisibly, <i>including</i> the "legend" attribute below, which otherwise mentions NA coding.                                                                                                                                                                                                         |
| eps              | absolute precision to be used at left and right boundary.                                                                                                                                                                                                                                                                                                                    |
| numeric.x        | logical indicating if x should be treated as numbers, otherwise as logical.                                                                                                                                                                                                                                                                                                  |
| corr             | logical. If TRUE, x contains correlations. The cutpoints are augmented by 0 and 1 and abs(x) is coded.                                                                                                                                                                                                                                                                       |
| show.max         | if TRUE, or of mode character, the maximal cutpoint is coded especially.                                                                                                                                                                                                                                                                                                     |
| show.min         | if TRUE, or of mode character, the minimal cutpoint is coded especially.                                                                                                                                                                                                                                                                                                     |
| abbr.colnames    | logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and x has no column names), the column names will all be empty, i.e., ""; otherwise if abbr.colnames is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to <code>abbreviate(*, minlength = abbr.colnames)</code> . |
| lower.triangular | logical. If TRUE and x is a matrix, only the <i>lower triangular</i> part of the matrix is coded as non-blank.                                                                                                                                                                                                                                                               |
| diag.lower.tri   | logical. If lower.triangular <i>and</i> this are TRUE, the <i>diagonal</i> part of the matrix is shown.                                                                                                                                                                                                                                                                      |

## Value

An atomic character object of class `noquote` and the same dimensions as x.

If legend is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

$$c_1 s_1 c_2 s_2 \dots s_n c_{n+1}$$

where  $c_j = \text{cutpoints}[j]$  and  $s_j = \text{symbols}[j]$ .

## Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

 cutpoints = c(0, .001,.01,.05, .1, 1),
 symbols = c("***", "**", "*", ".", " "))
noquote(cbind(P.val = format(pval), Signif = symp))

```

**t.test***Student's t-Test***Description**

Performs one and two sample t-tests on vectors of data.

**Usage**

```

t.test(x, ...)

Default S3 method:
t.test(x, y = NULL,
 alternative = c("two.sided", "less", "greater"),
 mu = 0, paired = FALSE, var.equal = FALSE,
 conf.level = 0.95, ...)

S3 method for class formula
t.test(formula, data, subset, na.action, ...)

```

**Arguments**

**x** a (non-empty) numeric vector of data values.

|             |                                                                                                                                                                                                                                            |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y           | an optional (non-empty) numeric vector of data values.                                                                                                                                                                                     |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.                                                                              |
| mu          | a number indicating the true value of the mean (or difference in means if you are performing a two sample test).                                                                                                                           |
| paired      | a logical indicating whether you want a paired t-test.                                                                                                                                                                                     |
| var.equal   | a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used. |
| conf.level  | confidence level of the interval.                                                                                                                                                                                                          |
| formula     | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.                                            |
| data        | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                 |
| subset      | an optional vector specifying a subset of observations to be used.                                                                                                                                                                         |
| na.action   | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                                 |
| ...         | further arguments to be passed to or from methods.                                                                                                                                                                                         |

## Details

The formula interface is only applicable for the 2-sample tests.

`alternative = "greater"` is the alternative that `x` has a larger mean than `y`.

If `paired` is TRUE then both `x` and `y` must be specified and they must be the same length. Missing values are silently removed (in pairs if `paired` is TRUE). If `var.equal` is TRUE then the pooled estimate of the variance is used. By default, if `var.equal` is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

## Value

A list with class "htest" containing the following components:

|             |                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------|
| statistic   | the value of the t-statistic.                                                                                                       |
| parameter   | the degrees of freedom for the t-statistic.                                                                                         |
| p.value     | the p-value for the test.                                                                                                           |
| conf.int    | a confidence interval for the mean appropriate to the specified alternative hypothesis.                                             |
| estimate    | the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.                       |
| null.value  | the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test. |
| alternative | a character string describing the alternative hypothesis.                                                                           |
| method      | a character string indicating what type of t-test was performed.                                                                    |
| data.name   | a character string giving the name(s) of the data.                                                                                  |

**See Also**

[prop.test](#)

**Examples**

```
require(graphics)

t.test(1:10, y = c(7:20)) # P = .00001855
t.test(1:10, y = c(7:20, 200)) # P = .1245 -- NOT significant anymore

Classical example: Students sleep data
plot(extra ~ group, data = sleep)
Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))
Formula interface
t.test(extra ~ group, data = sleep)
```

**Description**

Density, distribution function, quantile function and random generation for the t distribution with df degrees of freedom (and optional non-centrality parameter ncp).

**Usage**

```
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)
```

**Arguments**

|            |                                                                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, q       | vector of quantiles.                                                                                                                                             |
| p          | vector of probabilities.                                                                                                                                         |
| n          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required.                                                        |
| df         | degrees of freedom ( $> 0$ , maybe non-integer). <code>df = Inf</code> is allowed.                                                                               |
| ncp        | non-centrality parameter $\delta$ ; currently except for <code>rt()</code> , only for $\text{abs}(ncp) \leq 37.62$ . If omitted, use the central t distribution. |
| log, log.p | logical; if TRUE, probabilities p are given as log(p).                                                                                                           |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                                                                            |

## Details

The  $t$  distribution with  $\text{df} = \nu$  degrees of freedom has density

$$f(x) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)}(1 + x^2/\nu)^{-(\nu+1)/2}$$

for all real  $x$ . It has mean 0 (for  $\nu > 1$ ) and variance  $\frac{\nu}{\nu - 2}$  (for  $\nu > 2$ ).

The general *non-central t* with parameters  $(\nu, \delta) = (\text{df}, \text{ncp})$  is defined as the distribution of  $T_{\nu}(\delta) := (U + \delta)/\sqrt{V/\nu}$  where  $U$  and  $V$  are independent random variables,  $U \sim \mathcal{N}(0, 1)$  and  $V \sim \chi_{\nu}^2$  (see [Chisquare](#)).

The most used applications are power calculations for  $t$ -tests:

Let  $T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$  where  $\bar{X}$  is the [mean](#) and  $S$  the sample standard deviation ([sd](#)) of  $X_1, X_2, \dots, X_n$  which are i.i.d.  $\mathcal{N}(\mu, \sigma^2)$  Then  $T$  is distributed as non-central  $t$  with  $\text{df} = n - 1$  degrees of freedom and [non-centrality parameter](#)  $\text{ncp} = (\mu - \mu_0)\sqrt{n}/\sigma$ .

## Value

`dt` gives the density, `pt` gives the distribution function, `qt` gives the quantile function, and `rt` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rt`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

## Note

Supplying `ncp = 0` uses the algorithm for the non-central distribution, which is not the same algorithm used if `ncp` is omitted. This is to give consistent behaviour in extreme cases with values of `ncp` very near zero.

The code for non-zero `ncp` is principally intended to be used for moderate values of `ncp`: it will not be highly accurate, especially in the tails, for large values.

## Source

The central `dt` is computed via an accurate formula provided by Catherine Loader (see the reference in [dbinom](#)).

For the non-central case of `dt`, C code contributed by Claus Ekstrøm based on the relationship (for  $x \neq 0$ ) to the cumulative distribution.

For the central case of `pt`, a normal approximation in the tails, otherwise via [pbeta](#).

For the non-central case of `pt` based on a C translation of

Lenth, R. V. (1989). *Algorithm AS 243 — Cumulative distribution function of the non-central t distribution*, *Applied Statistics* **38**, 185–189.

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

For central `qt`, a C translation of

Hill, G. W. (1970) Algorithm 396: Student's t-quantiles. *Communications of the ACM*, **13**(10), 619–620.

altered to take account of

Hill, G. W. (1981) Remark on Algorithm 396, *ACM Transactions on Mathematical Software*, **7**, 250–1.

The non-central case is done by inversion.

## Examples

```
require(graphics)

1 - pt(1:5, df = 1)
qt(.975, df = c(1:10,20,50,100,1000))

tt <- seq(0, 10, len = 21)
ncp <- seq(0, 6, len = 31)
ptn <- outer(tt, ncp, function(t, d) pt(t, df = 3, ncp = d))
t.tit <- "Non-central t - Probabilities"
image(tt, ncp, ptn, zlim = c(0,1), main = t.tit)
persp(tt, ncp, ptn, zlim = 0:1, r = 2, phi = 20, theta = 200, main = t.tit,
 xlab = "t", ylab = "non-centrality parameter",
 zlab = "Pr(T <= t)")

plot(function(x) dt(x, df = 3, ncp = 2), -3, 11, ylim = c(0, 0.32),
 main = "Non-central t - Density", yaxs = "i")
```

## termplot

### Plot Regression Terms

## Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

## Usage

```
termplot(model, data = NULL, envir = environment(formula(model)),
 partial.resid = FALSE, rug = FALSE,
 terms = NULL, se = FALSE,
 xlabs = NULL, ylabs = NULL, main = NULL,
 col.term = 2, lwd.term = 1.5,
 col.se = "orange", lty.se = 2, lwd.se = 1,
 col.res = "gray", cex = 1, pch = par("pch"),
```

```
col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
ask = dev.interactive() && nb.fig < n.tms,
use.factor.levels = TRUE, smooth = NULL, ylim = "common",
plot = TRUE, transform.x = FALSE, ...)
```

## Arguments

|                               |                                                                                                                                                                                                                                                                                                      |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model                         | fitted model object                                                                                                                                                                                                                                                                                  |
| data                          | data frame in which variables in model can be found                                                                                                                                                                                                                                                  |
| envir                         | environment in which variables in model can be found                                                                                                                                                                                                                                                 |
| partial.resid                 | logical; should partial residuals be plotted?                                                                                                                                                                                                                                                        |
| rug                           | add <a href="#">rugplots</a> (jittered 1-d histograms) to the axes?                                                                                                                                                                                                                                  |
| terms                         | which terms to plot (default NULL means all terms); a vector passed to <a href="#">predict</a> (..., term = "terms", terms = *).                                                                                                                                                                     |
| se                            | plot pointwise standard errors?                                                                                                                                                                                                                                                                      |
| xlabs                         | vector of labels for the x axes                                                                                                                                                                                                                                                                      |
| ylabs                         | vector of labels for the y axes                                                                                                                                                                                                                                                                      |
| main                          | logical, or vector of main titles; if TRUE, the model's call is taken as main title, NULL or FALSE mean no titles.                                                                                                                                                                                   |
| col.term, lwd.term            | color and line width for the 'term curve', see <a href="#">lines</a> .                                                                                                                                                                                                                               |
| col.se, lty.se, lwd.se        | color, line type and line width for the 'twice-standard-error curve' when se = TRUE.                                                                                                                                                                                                                 |
| col.res, cex, pch             | color, plotting character expansion and type for partial residuals, when partial.resid = TRUE, see <a href="#">points</a> .                                                                                                                                                                          |
| ask                           | logical; if TRUE, the user is asked before each plot, see <a href="#">par</a> (ask=.).                                                                                                                                                                                                               |
| use.factor.levels             | Should x-axis ticks use factor levels or numbers for factor terms?                                                                                                                                                                                                                                   |
| smooth                        | NULL or a function with the same arguments as <a href="#">panel.smooth</a> to draw a smooth through the partial residuals for non-factor terms                                                                                                                                                       |
| lty.smth, col.smth, span.smth | Passed to smooth                                                                                                                                                                                                                                                                                     |
| ylim                          | an optional range for the y axis, or "common" when a range sufficient for all the plot will be computed, or "free" when limits are computed for each plot.                                                                                                                                           |
| plot                          | if set to FALSE plots are not produced: instead a list is returned containing the data that would have been plotted.                                                                                                                                                                                 |
| transform.x                   | logical vector; if an element (recycled as necessary) is TRUE, partial residuals for the corresponding term are plotted against transformed values. The model response is then a straight line, allowing a ready comparison against the data or against the curve obtained from smooth-panel.smooth. |
| ...                           | other graphical parameters.                                                                                                                                                                                                                                                                          |

## Details

The model object must have a predict method that accepts type = terms, e.g., `glm` in the **stats** package, `coxph` and `survreg` in the **survival** package.

For the partial.resid = TRUE option model must have a `residuals` method that accepts type = "partial", which `lm` and `glm` do.

The data argument should rarely be needed, but in some cases `termplot` may be unable to reconstruct the original data frame. Using na.action=na.exclude makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The plot = FALSE option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

## Value

For plot = FALSE, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables x, y, and optionally the pointwise standard errors se. For continuous predictors x will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute "constant" copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

## See Also

For (generalized) linear models, `plot.lm` and `predict.glm`.

## Examples

```
require(graphics)

hadsplines <- "package:splines" %in% search()
if(!hadsplines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)

par(mfrow = c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot(", deparse(model$call), " ...")"))
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!hadsplines & rs) detach("package:splines")

if (require(MASS)) {
 hills.lm <- lm(log(time) ~ log(climb)+log(dist), data=hills)
 termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth,
 terms = "log(dist)", main = "Original")
 termplot(hills.lm, transform.x = TRUE, partial.resid = TRUE,
 terms = "log(dist)", main = "Transformed",
 smooth=panel.smooth)
}
```

## Description

The function `terms` is a generic function which can be used to extract *terms* objects from various kinds of R data objects.

## Usage

```
terms(x, ...)
```

## Arguments

- |     |                                                    |
|-----|----------------------------------------------------|
| x   | object used to select a method to dispatch.        |
| ... | further arguments passed to or from other methods. |

## Details

There are methods for classes "aoolist", and "terms" "formula" (see `terms.formula`): the default method just extracts the `terms` component of the object, or failing that a "terms" attribute (as used by `model.frame`).

There are `print` and `labels` methods for class "terms": the latter prints the term labels (see `terms.object`).

## Value

An object of class `c("terms", "formula")` which contains the *terms* representation of a symbolic model. See `terms.object` for its structure.

|---------------|------------------------------------------------|
| terms.formula | <i>Construct a terms Object from a Formula</i> |
|---------------|------------------------------------------------|

---

## Description

This function takes a formula and some optional arguments and constructs a `terms` object. The `terms` object can then be used to construct a `model.matrix`.

## Usage

```
S3 method for class formula
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
 keep.order = FALSE, simplify = FALSE, ...,
 allowDotAsName = FALSE)
```

## Arguments

|                             |                                                                                                                                                                                                                                                                                  |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>              | a formula.                                                                                                                                                                                                                                                                       |
| <code>specials</code>       | which functions in the formula should be marked as special in the <code>terms</code> object?<br>A character vector or NULL.                                                                                                                                                      |
| <code>abb</code>            | Not implemented in R.                                                                                                                                                                                                                                                            |
| <code>data</code>           | a data frame from which the meaning of the special symbol <code>.</code> can be inferred. It is unused if there is no <code>.</code> in the formula.                                                                                                                             |
| <code>neg.out</code>        | Not implemented in R.                                                                                                                                                                                                                                                            |
| <code>keep.order</code>     | a logical value indicating whether the terms should keep their positions. If FALSE the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified. |
| <code>simplify</code>       | should the formula be expanded and simplified, the pre-1.7.0 behaviour?                                                                                                                                                                                                          |
| <code>...</code>            | further arguments passed to or from other methods.                                                                                                                                                                                                                               |
| <code>allowDotAsName</code> | normally <code>.</code> in a formula refers to the remaining variables contained in <code>data</code> . Exceptionally, <code>.</code> can be treated as a name for non-standard uses of formulae.                                                                                |

## Details

Not all of the options work in the same way that they do in S and not all are implemented.

## Value

A `terms.object` object is returned. The object itself is the re-ordered (unless `keep.order = TRUE`) formula. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

## Description

An object of class `terms` holds information about a model. Usually the model was specified in terms of a `formula` and that formula was used to determine the `terms` object.

### Value

The object itself is simply the formula supplied to the call of [terms.formula](#). The object has a number of attributes and they are used to construct the model frame:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>factors</code>     | A matrix of variables by terms showing which variables appear in which terms. The entries are 0 if the variable does not occur in the term, 1 if it does occur and should be coded by contrasts, and 2 if it occurs and should be coded via dummy variables for all levels (as when an intercept or lower-order term is missing). If there are no terms other than an intercept and offsets, this is <code>numeric(0)</code> . |
| <code>term.labels</code> | A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms. Non-syntactic names will be quoted by backticks: this makes it easier to reconstruct the formula from the term labels.                                                                                                                                               |
| <code>variables</code>   | A call to <code>list</code> of the variables in the model.                                                                                                                                                                                                                                                                                                                                                                     |
| <code>intercept</code>   | Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.                                                                                                                                                                                                                                                                                                                                |
| <code>order</code>       | A vector of the same length as <code>term.labels</code> indicating the order of interaction for each term.                                                                                                                                                                                                                                                                                                                     |
| <code>response</code>    | The index of the variable (in <code>variables</code> ) of the response (the left hand side of the formula). Zero, if there is no response.                                                                                                                                                                                                                                                                                     |
| <code>offset</code>      | If the model contains <code>offset</code> terms there is an <code>offset</code> attribute indicating which variable(s) are offsets                                                                                                                                                                                                                                                                                             |
| <code>specials</code>    | If a <code>specials</code> argument was given to <a href="#">terms.formula</a> there is a <code>specials</code> attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the <code>variables</code> attribute which contain these special functions.                                                                                         |
| <code>dataClasses</code> | optional. A named character vector giving the classes (as given by <a href="#">.MFclass</a> ) of the variables used in a fit.                                                                                                                                                                                                                                                                                                  |

The object has class `c("terms", "formula")`.

### Note

These objects are different from those found in S. In particular there is no `formula` attribute: instead the object is itself a formula. (Thus, the mode of a `terms` object is different.)

Examples of the `specials` argument can be seen in the `aov` and `coxph` functions, the latter from package `survival`.

### See Also

[terms](#), [formula](#).

### Examples

```
use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
Note that the "factors" attribute has variables as row names
and term labels as column names, both as character vectors.
attr(tf, "specials") # index s variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]
```

---

```
we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

---

|      |                                      |
|------|--------------------------------------|
| time | <i>Sampling Times of Time Series</i> |
|------|--------------------------------------|

---

## Description

time creates the vector of times at which a time series was sampled.  
 cycle gives the positions in the cycle of each observation.  
 frequency returns the number of samples per unit time and deltat the time interval between observations (see [ts](#)).

## Usage

```
time(x, ...)
Default S3 method:
time(x, offset = 0, ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)
```

## Arguments

|                     |                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | a univariate or multivariate time-series, or a vector or matrix.                                                                                                  |
| <code>offset</code> | can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval. |
| <code>...</code>    | extra arguments for future methods.                                                                                                                               |

## Details

These are all generic functions, which will use the `tsp` attribute of `x` if it exists. `time` and `cycle` have methods for class [ts](#) that coerce the result to that class.

**toeplitz***Form Symmetric Toeplitz Matrix*

---

**Description**

Forms a symmetric Toeplitz matrix given its first row.

**Usage**

```
toeplitz(x, ...)
```

**Arguments**

|     |                                                       |
|-----|-------------------------------------------------------|
| x   | the first row to form the Toeplitz matrix.            |
| ... | potential further arguments (for methods); none here. |

**Value**

The Toeplitz matrix.

**Author(s)**

A. Trapletti

**Examples**

```
x <- 1:5
toeplitz (x)
```

---

**ts***Time-Series Objects*

---

**Description**

The function `ts` is used to create time-series objects.

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

**Usage**

```
ts(data = NA, start = 1, end = numeric(), frequency = 1,
 deltat = 1, ts.eps = getOption("ts.eps"), class = , names =)
as.ts(x, ...)
is.ts(x)
```

## Arguments

|                        |                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via <code>data.matrix</code> . (See also ‘Details’.)                                                                    |
| <code>start</code>     | the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form. |
| <code>end</code>       | the time of the last observation, specified in the same way as <code>start</code> .                                                                                                                                             |
| <code>frequency</code> | the number of observations per unit of time.                                                                                                                                                                                    |
| <code>deltat</code>    | the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of <code>frequency</code> or <code>deltat</code> should be provided.                                                 |
| <code>ts.eps</code>    | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> .                                                                                              |
| <code>class</code>     | class to be given to the result, or <code>NULL</code> or “ <code>none</code> ”. The default is “ <code>ts</code> ” for a single series, <code>c("mts", "ts", "matrix")</code> for multiple series.                              |
| <code>names</code>     | a character vector of names for the series in a multiple series: defaults to the <code>colnames</code> of <code>data</code> , or <code>Series 1, Series 2, ...</code> .                                                         |
| <code>x</code>         | an arbitrary R object.                                                                                                                                                                                                          |
| <code>...</code>       | arguments passed to methods (unused for the default method).                                                                                                                                                                    |

## Details

The function `ts` is used to create time-series objects. These are vector or matrices with class of “`ts`” (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix `data` is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class “`ts`” has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see [window](#)). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class “`ts`”.

The value of argument `frequency` is used when the series is sampled an integral number of times in each unit time interval. For example, one could use a value of 7 for `frequency` when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) `print` methods to imply a quarterly and monthly series respectively.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts` tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

## See Also

`tsp`, `frequency`, `start`, `end`, `time`, `window`; `print.ts`, the print method for time series objects; `plot.ts`, the plot method for time series objects.

For other definitions of ‘time series’ (e.g., time-ordered observations) see the CRAN task view at <http://cran.r-project.org/web/views/TimeSeries.html>.

## Examples

```
require(graphics)

ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
print.ts(.)
Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
 start = c(1954, 7), frequency = 12)
plot(gnp) # using plot.ts for time-series plot

Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z)
head(z) # as "matrix"
plot(z)
plot(z, plot.type = "single", lty = 1:3)

A phase plot:
plot(nhtemp, c(nhtemp[-1], NA), cex = .8, col = "blue",
 main = "Lag plot of New Haven temperatures")
a clearer way to do this would be
Not run:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
 main = "Lag plot of New Haven temperatures")

End(Not run)
```

## Description

Methods for objects of class “`ts`”, typically the result of `ts`.

## Usage

```
S3 method for class ts
diff(x, lag = 1, differences = 1, ...)

S3 method for class ts
na.omit(object, ...)
```

**Arguments**

- |                          |                                                                  |
|--------------------------|------------------------------------------------------------------|
| <code>x</code>           | an object of class "ts" containing the values to be differenced. |
| <code>lag</code>         | an integer indicating which lag to use.                          |
| <code>differences</code> | an integer indicating the order of the difference.               |
| <code>object</code>      | a univariate or multivariate time series.                        |
| <code>...</code>         | further arguments to be passed to or from methods.               |

**Details**

The `na.omit` method omits initial and final segments with missing values in one or more of the series. 'Internal' missing values will lead to failure.

**Value**

For the `na.omit` method, a time series without missing values. The class of `object` will be preserved.

**See Also**

[diff](#); [na.omit](#), [na.fail](#), [na.contiguous](#).

`ts.plot`

*Plot Multiple Time Series*

**Description**

Plot several time series on a common plot. Unlike [plot.ts](#) the series can have a different time bases, but they should have the same frequency.

**Usage**

```
ts.plot(..., gpars = list())
```

**Arguments**

- |                    |                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>   | one or more univariate or multivariate time series.                                                                             |
| <code>gpars</code> | list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in ... . |

**Value**

None.

**Note**

Although this can be used for a single time series, `plot` is easier to use and is preferred.

**See Also**

[plot.ts](#)

## Examples

```
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
 gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

---

ts.union

*Bind Two or More Time Series*

---

## Description

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

## Usage

```
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```

## Arguments

|        |                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------|
| ...    | two or more univariate or multivariate time series, or objects which can coerced to time series. |
| dframe | logical; if TRUE return the result as a data frame.                                              |

## Details

As a special case, ... can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

## Value

A time series object if dframe is FALSE, otherwise a data frame.

## See Also

[cbind](#).

## Examples

```
ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```

---

**tsdiag***Diagnostic Plots for Time-Series Fits*

---

**Description**

A generic function to plot time-series diagnostics.

**Usage**

```
tsdiag(object, gof.lag, ...)
```

**Arguments**

|                      |                                                                   |
|----------------------|-------------------------------------------------------------------|
| <code>object</code>  | a fitted time-series model                                        |
| <code>gof.lag</code> | the maximum number of lags for a Portmanteau goodness-of-fit test |
| <code>...</code>     | further arguments to be passed to particular methods              |

**Details**

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to `gof.lag`.

The methods for `arima` and `StructTS` objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

**Value**

None. Diagnostics are plotted.

**See Also**

[arima](#), [StructTS](#), [Box.test](#)

**Examples**

```
Not run: require(graphics)

fit <- arima(lh, c(1,0,0))
tsdiag(fit)

see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdiag(fit)

End(Not run)
```

---

**tsp***Tsp Attribute of Time-Series-like Objects*

---

## Description

`tsp` returns the `tsp` attribute (or `NULL`). It is included for compatibility with S version 2. `tsp<-` sets the `tsp` attribute. `hasTsp` ensures `x` has a `tsp` attribute, by adding one if needed.

## Usage

```
tsp(x)
tsp(x) <- value
hasTsp(x)
```

## Arguments

- |                    |                                                               |
|--------------------|---------------------------------------------------------------|
| <code>x</code>     | a vector or matrix or univariate or multivariate time-series. |
| <code>value</code> | a numeric vector of length 3 or <code>NULL</code> .           |

## Details

The `tsp` attribute was previously described here as `c(start(x), end(x), frequency(x))`, but this is incorrect. It gives the start time *in time units*, the end time and the frequency.

Assignments are checked for consistency.

Assigning `NULL` which removes the `tsp` attribute *and* any "`ts`" (or "`mts`") class of `x`.

**tsSmooth***Use Fixed-Interval Smoothing on Time Series*

---

## Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

## Usage

```
tsSmooth(object, ...)
```

**Arguments**

- object            a time-series fit. Currently only class "[StructTS](#)" is supported  
 ...              possible arguments for future methods.

**Value**

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

**Author(s)**

B. D. Ripley

Tukey

*The Studentized Range Distribution*

**Description**

Functions of the distribution of the studentized range,  $R/s$ , where  $R$  is the range of a standard normal sample and  $df \times s^2$  is independently distributed as chi-squared with  $df$  degrees of freedom, see [pchisq](#).

**Usage**

```
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
ptukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```

**Arguments**

- |            |                                                                                       |
|------------|---------------------------------------------------------------------------------------|
| q          | vector of quantiles.                                                                  |
| p          | vector of probabilities.                                                              |
| nmeans     | sample size for range (same for each group).                                          |
| df         | degrees of freedom for $s$ (see below).                                               |
| nranges    | number of <i>groups</i> whose <b>maximum</b> range is considered.                     |
| log.p      | logical; if TRUE, probabilities p are given as log(p).                                |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ . |

**Details**

If  $n_g = \text{nranges}$  is greater than one,  $R$  is the *maximum* of  $n_g$  groups of nmeans observations each.

**Value**

`ptukey` gives the distribution function and `qtukey` its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical parameters. The other numerical parameters are recycled to that length. Only the first elements of the logical parameters are used.

**Note**

A Legendre 16-point formula is used for the integral of `ptukey`. The computations are relatively expensive, especially for `qtukey` which uses a simple secant method for finding the inverse of `ptukey`. `qtukey` will be accurate to the 4th decimal place.

**Source**

`qtukey` is in part adapted from Odeh and Evans (1974).

**See Also**

[Distributions](#) for standard distributions, including `pnorm` and `qnorm` for the corresponding functions for the normal distribution.

**Examples**

```
if(interactive())
 curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
 (ptt <- ptukey(0:10, 2, df = 5))
 (qtt <- qtukey(.95, 2, df = 2:11))
 ## The precision may be not much more than about 8 digits:
 summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))
```

**Description**

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey's 'Honest Significant Difference' method.

**Usage**

```
TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)
```

### Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | A fitted model object, usually an <a href="#">aov</a> fit.                                                                                                                                                                                                                                                                                           |
| <code>which</code>      | A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.                                                                                                                                                                                                                        |
| <code>ordered</code>    | A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If <code>ordered</code> is true then the calculated differences in the means will all be positive. The significant differences will be those for which the <code>lwr</code> end point is positive. |
| <code>conf.level</code> | A numeric value between zero and one giving the family-wise confidence level to use.                                                                                                                                                                                                                                                                 |
| <code>...</code>        | Optional additional arguments. None are used at present.                                                                                                                                                                                                                                                                                             |

### Details

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If `which` specifies non-factor terms these will be dropped with a warning: if no terms are left this is a an error.

In R 2.15.2 and earlier the results were NA for fits with `na.action` methods such as [na.exclude](#).

### Value

A list of class `c("multicomp", "TukeyHSD")`, with one component for each term requested in `which`. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p adj` giving the p-value after adjustment for the multiple comparisons.

There are `print` and `plot` methods for class `"TukeyHSD"`. The `plot` method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

## Examples

```
require(graphics)

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))
```

## Uniform

### *The Uniform Distribution*

## Description

These functions provide information about the uniform distribution on the interval from `min` to `max`. `dunif` gives the density, `punif` gives the distribution function `qunif` gives the quantile function and `runit` generates random deviates.

## Usage

```
dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)
```

## Arguments

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                      |
| <code>p</code>          | vector of probabilities.                                                                                  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>min, max</code>   | lower and upper limits of the distribution. Must be finite.                                               |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                         |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

## Details

If `min` or `max` are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

$$f(x) = \frac{1}{\max - \min}$$

for  $\min \leq x \leq \max$ .

For the case of  $u := \min == \max$ , the limit case of  $X \equiv u$  is assumed, although there is no density in that case and `dunif` will return NaN (the error condition).

`runif` will not generate either of the extreme values unless `max = min` or `max-min` is small compared to `min`, and in particular not for the default arguments.

**Value**

`dunif` gives the density, `punif` gives the distribution function, `qunif` gives the quantile function, and `runeif` generates random deviates.

The length of the result is determined by `n` for `runeif`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Note**

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See [.Random.seed](#) for more information on R's random number generation algorithms.

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**

[RNG](#) about random number generation in R.

[Distributions](#) for other standard distributions.

**Examples**

```
u <- runif(20)

The following relations always hold :
punif(u) == u
dunif(u) == 1

var(runeif(10000)) #~ = 1/12 = .08333
```

**Description**

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

**Usage**

```
uniroot(f, interval, ...,
 lower = min(interval), upper = max(interval),
 f.lower = f(lower, ...), f.upper = f(upper, ...),
 tol = .Machine$double.eps^0.25, maxiter = 1000)
```

### Arguments

|                                             |                                                                                                                                                                                                                               |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>                              | the function for which the root is sought.                                                                                                                                                                                    |
| <code>interval</code>                       | a vector containing the end-points of the interval to be searched for the root.                                                                                                                                               |
| <code>...</code>                            | additional named or unnamed arguments to be passed to <code>f</code>                                                                                                                                                          |
| <code>lower</code> , <code>upper</code>     | the lower and upper end points of the interval to be searched.                                                                                                                                                                |
| <code>f.lower</code> , <code>f.upper</code> | the same as <code>f(upper)</code> and <code>f(lower)</code> , respectively. Passing these values from the caller where they are often known is more economical as soon as <code>f()</code> contains non-trivial computations. |
| <code>tol</code>                            | the desired accuracy (convergence tolerance).                                                                                                                                                                                 |
| <code>maxiter</code>                        | the maximum number of iterations.                                                                                                                                                                                             |

### Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero).

The function uses Fortran subroutine ““zeroin”” (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if `f(x) == 0` or the change in `x` for one step of the algorithm is less than `tol` (plus an allowance for representation error in `x`).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

`f` will be called as `f(x, ...)` for a numeric value of `x`.

The argument passed to `f` has special semantics and used to be shared between calls. The function should not copy it.

### Value

A list with at least four components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for `root`. (If the root occurs at one of the endpoints, the estimated precision is NA.)

Further components may be added in future.

### Source

Based on ‘zeroin.c’ in <http://www.netlib.org/c/brent.shar>.

### References

Brent, R. (1973) *Algorithms for Minimization without Derivatives*. Englewood Cliffs, NJ: Prentice-Hall.

### See Also

[polyroot](#) for all complex roots of a polynomial; [optimize](#), [nlm](#).

## Examples

```
require(utils) # for str

some platforms hit zero exactly on the first step:
if so the estimated precision is 2/3.
f <- function (x, a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

handheld calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
 tol = 0.0001))
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
 tol = 1e-10))

Find the smallest value x for which exp(x) > 0 (numerically):
r <- uniroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root) # = 0, but not for r$root * 0.999...
minexp <- r$root * (1 - 10*.Machine$double.eps)
exp(minexp) # typically denormalized
```

update

*Update and Re-fit a Model Call*

## Description

`update` will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call `update` with only one argument, for example if the data frame has been corrected.

“Extracting the call” in `update()` and similar functions uses `getCall()` which itself is a (S3) generic function with a default method that simply gets `x$call`.

Because of this, `update()` will often work (via its default method) on new model classes, either automatically, or by providing a simple `getCall()` method for that class.

## Usage

```
update(object, ...)
Default S3 method:
update(object, formula., ..., evaluate = TRUE)

getCall(x, ...)
```

## Arguments

|                        |                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>object, x</code> | An existing fit from a model function such as <code>lm</code> , <code>glm</code> and many others.                             |
| <code>formula.</code>  | Changes to the formula – see <code>update.formula</code> for details.                                                         |
| <code>...</code>       | Additional arguments to the call, or arguments with changed values. Use <code>name = NULL</code> to remove the argument name. |
| <code>evaluate</code>  | If true evaluate the new call else return the call.                                                                           |

**Value**

If evaluate = TRUE the fitted object, otherwise the updated call.

options(oldcon)
```

**Description**

`update.formula` is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

**Usage**

```
S3 method for class formula
update(old, new, ...)
```

**Arguments**

- `old` a model formula to be updated.
- `new` a formula giving a template which specifies how to update.
- `...` further arguments passed to or from other methods.

## Details

Either or both of `old` and `new` can be objects such as length-one character vectors which can be coerced to a formula via `as.formula`.

The function works by first identifying the *left-hand side* and *right-hand side* of the `old` formula. It then examines the `new` formula and substitutes the *lhs* of the `old` formula for any occurrence of ‘`:`’ on the left of `new`, and substitutes the *rhs* of the `old` formula for any occurrence of ‘`:`’ on the right of `new`. The result is then simplified via `terms.formula(simplify = TRUE)`.

## Value

The updated formula is returned. The environment of the result is that of `old`.

## See Also

`terms`, `model.matrix`.

## Examples

```
update(y ~ x, ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ .) #> log(y) ~ x
```

`var.test`

*F Test to Compare Two Variances*

## Description

Performs an F test to compare the variances of two samples from normal populations.

## Usage

```
var.test(x, ...)

Default S3 method:
var.test(x, y, ratio = 1,
 alternative = c("two.sided", "less", "greater"),
 conf.level = 0.95, ...)

S3 method for class formula
var.test(formula, data, subset, na.action, ...)
```

## Arguments

|                          |                                                                                                                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>        | numeric vectors of data values, or fitted linear model objects (inheriting from class “ <code>lm</code> ”).                                                                                                |
| <code>ratio</code>       | the hypothesized ratio of the population variances of <code>x</code> and <code>y</code> .                                                                                                                  |
| <code>alternative</code> | a character string specifying the alternative hypothesis, must be one of “ <code>two.sided</code> ” (default), “ <code>greater</code> ” or “ <code>less</code> ”. You can specify just the initial letter. |
| <code>conf.level</code>  | confidence level for the returned confidence interval.                                                                                                                                                     |

|           |                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.                         |
| data      | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| subset    | an optional vector specifying a subset of observations to be used.                                                                                                                                                      |
| na.action | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                              |
| ...       | further arguments to be passed to or from methods.                                                                                                                                                                      |

## Details

The null hypothesis is that the ratio of the variances of the populations from which `x` and `y` were drawn, or in the data to which the linear models `x` and `y` were fitted, is equal to `ratio`.

## Value

A list with class "htest" containing the following components:

|             |                                                                          |
|-------------|--------------------------------------------------------------------------|
| statistic   | the value of the F test statistic.                                       |
| parameter   | the degrees of the freedom of the F distribution of the test statistic.  |
| p.value     | the p-value of the test.                                                 |
| conf.int    | a confidence interval for the ratio of the population variances.         |
| estimate    | the ratio of the sample variances of <code>x</code> and <code>y</code> . |
| null.value  | the ratio of population variances under the null.                        |
| alternative | a character string describing the alternative hypothesis.                |
| method      | the character string "F test to compare two variances".                  |
| data.name   | a character string giving the names of the data.                         |

## See Also

`bartlett.test` for testing homogeneity of variances in more than two samples from normal distributions; `ansari.test` and `mood.test` for two rank based (nonparametric) two-sample tests for difference in scale.

## Examples

```
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y) # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
```

---

**varimax***Rotation Methods for Factor Analysis*

---

**Description**

These functions ‘rotate’ loading matrices in factor analysis.

**Usage**

```
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

**Arguments**

|           |                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | A loadings matrix, with $p$ rows and $k < p$ columns                                                                                             |
| m         | The power used the target for promax. Values of 2 to 4 are recommended.                                                                          |
| normalize | logical. Should Kaiser normalization be performed? If so the rows of x are re-scaled to unit length before rotation, and scaled back afterwards. |
| eps       | The tolerance for stopping: the relative change in the sum of singular values.                                                                   |

**Details**

These seek a ‘rotation’ of the factors  $x \times T$  that aims to clarify the structure of the loadings matrix. The matrix  $T$  is a rotation (possibly with reflection) for varimax, but a general linear transformation for promax, with the variance of the factors being preserved.

**Value**

A list with components

|          |                                                                         |
|----------|-------------------------------------------------------------------------|
| loadings | The ‘rotated’ loadings matrix, $x \times rotmat$ , of class “loadings”. |
| rotmat   | The ‘rotation’ matrix.                                                  |

varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

---

vcov

*Calculate Variance-Covariance Matrix for a Fitted Model Object*

---

## Description

Returns the variance-covariance matrix of the main parameters of a fitted model object.

## Usage

```
vcov(object, ...)
```

## Arguments

- |        |                                                                                                                                       |
|--------|---------------------------------------------------------------------------------------------------------------------------------------|
| object | a fitted model object, typically. Sometimes also a <a href="#">summary()</a> object of such a fitted model.                           |
| ...    | additional arguments for method functions. For the <a href="#">glm</a> method this can be used to pass a <i>dispersion</i> parameter. |

## Details

This is a generic function. Functions with names beginning in `vcov.` will be methods for this function. Classes with methods for this function include: `lm`, `m1m`, `glm`, `nls`, `summary.lm`, `summary.glm`, `negbin`, `polr`, `r1m` (in package **MASS**), `multinom` (in package **nnet**) `gls`, `lme` (in package **nlme**), `coxph` and `survreg` (in package **survival**).

(`vcov()` methods for `summary` objects allow more efficient and still encapsulated access when both `summary(mod)` and `vcov(mod)` are needed.)

## Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the `coef` method.

---

Weibull*The Weibull Distribution*

---

**Description**

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters `shape` and `scale`.

**Usage**

```
dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)
```

**Arguments**

|                           |                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>         | vector of quantiles.                                                                                      |
| <code>p</code>            | vector of probabilities.                                                                                  |
| <code>n</code>            | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>shape, scale</code> | shape and scale parameters, the latter defaulting to 1.                                                   |
| <code>log, log.p</code>   | logical; if TRUE, probabilities p are given as log(p).                                                    |
| <code>lower.tail</code>   | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

The Weibull distribution with `shape` parameter  $a$  and `scale` parameter  $\sigma$  has density given by

$$f(x) = (a/\sigma)(x/\sigma)^{a-1} \exp(-(x/\sigma)^a)$$

for  $x > 0$ . The cumulative distribution function is  $F(x) = 1 - \exp(-(x/\sigma)^a)$  on  $x > 0$ , the mean is  $E(X) = \sigma\Gamma(1 + 1/a)$ , and the  $Var(X) = \sigma^2(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2)$ .

**Value**

`dweibull` gives the density, `pweibull` gives the distribution function, `qweibull` gives the quantile function, and `rweibull` generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rweibull`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Note**

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is

```
-pweibull(t, a, b, lower = FALSE, log = TRUE)
```

which is just  $H(t) = (t/b)^a$ .

## Source

[dpq]weibull are calculated directly from the definitions. rweibull uses inversion.

## See Also

[Distributions](#) for other standard distributions, including the [Exponential](#) which is a special case of the Weibull distribution.

## Examples

```
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
 -(x/pi)^2.5, tol = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

---

weighted.mean

*Weighted Arithmetic Mean*

---

## Description

Compute a weighted mean.

## Usage

```
weighted.mean(x, w, ...)
Default S3 method:
weighted.mean(x, w, ..., na.rm = FALSE)
```

## Arguments

- x an object containing the values whose weighted mean is to be computed.
- w a numerical vector of weights the same length as x giving the weights to use for elements of x.
- ... arguments to be passed to or from methods.
- na.rm a logical value indicating whether NA values in x should be stripped before the computation proceeds.

## Details

This is a generic function and methods can be defined for the first argument  $x$ : apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which [, multiplication, division and `sum` have suitable methods, including complex vectors.

If  $w$  is missing then all elements of  $x$  are given the same weight, otherwise the weights coerced to numeric by `as.numeric` and normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in  $w$  are not handled specially and so give a missing value as the result. However, as from R 2.11.0 zero weights *are* handled specially and the corresponding  $x$  values are omitted from the sum.

## Value

For the default method, a length-one numeric vector.

## See Also

`mean`

## Examples

```
GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

`weighted.residuals`      *Compute Weighted Residuals*

## Description

Computed weighted residuals from a linear model fit.

## Usage

```
weighted.residuals(obj, drop0 = TRUE)
```

## Arguments

- |                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <code>obj</code>   | R object, typically of class <code>lm</code> or <code>glm</code> . |
| <code>drop0</code> | logical. If TRUE, drop all cases with <code>weights == 0</code> .  |

## Details

Weighted residuals are based on the deviance residuals, which for a `lm` fit are the raw residuals  $R_i$  multiplied by  $\sqrt{w_i}$ , where  $w_i$  are the weights as specified in `lm`'s call.

Dropping cases with weights zero is compatible with `influence` and related functions.

**Value**

Numeric vector of length  $n'$ , where  $n'$  is the number of non-0 weights (`drop0 = TRUE`) or the number of observations, otherwise.

**See Also**

[residuals](#), [lm.influence](#), etc.

**Examples**

```
following on from example(lm)

all.equal(weighted.residuals(lm.D9),
 residuals(lm.D9))
x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

---

weights

*Extract Model Weights*

---

**Description**

`weights` is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of [napredict](#) methods to compensate for the omission of missing values. The default methods does so.

**Usage**

```
weights(object, ...)
```

**Arguments**

|        |                                                                    |
|--------|--------------------------------------------------------------------|
| object | an object for which the extraction of model weights is meaningful. |
| ...    | other arguments passed to methods.                                 |

**Value**

Weights extracted from the object `object`: the default method looks for component "weights" and if not `NULL` calls [napredict](#) on it.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

---

**wilcox.test***Wilcoxon Rank Sum and Signed Rank Tests*

---

**Description**

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as ‘Mann-Whitney’ test.

**Usage**

```
wilcox.test(x, ...)

Default S3 method:
wilcox.test(x, y = NULL,
 alternative = c("two.sided", "less", "greater"),
 mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
 conf.int = FALSE, conf.level = 0.95, ...)

S3 method for class formula
wilcox.test(formula, data, subset, na.action, ...)
```

**Arguments**

|                    |                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>           | numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.                                                                                                                   |
| <b>y</b>           | an optional numeric vector of data values: as with <b>x</b> non-finite values will be omitted.                                                                                                                 |
| <b>alternative</b> | a character string specifying the alternative hypothesis, must be one of “two.sided” (default), “greater” or “less”. You can specify just the initial letter.                                                  |
| <b>mu</b>          | a number specifying an optional parameter used to form the null hypothesis. See ‘Details’.                                                                                                                     |
| <b>paired</b>      | a logical indicating whether you want a paired test.                                                                                                                                                           |
| <b>exact</b>       | a logical indicating whether an exact p-value should be computed.                                                                                                                                              |
| <b>correct</b>     | a logical indicating whether to apply continuity correction in the normal approximation for the p-value.                                                                                                       |
| <b>conf.int</b>    | a logical indicating whether a confidence interval should be computed.                                                                                                                                         |
| <b>conf.level</b>  | confidence level of the interval.                                                                                                                                                                              |
| <b>formula</b>     | a formula of the form <b>lhs ~ rhs</b> where <b>lhs</b> is a numeric variable giving the data values and <b>rhs</b> a factor with two levels giving the corresponding groups.                                  |
| <b>data</b>        | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <b>formula</b> . By default the variables are taken from <b>environment(formula)</b> . |
| <b>subset</b>      | an optional vector specifying a subset of observations to be used.                                                                                                                                             |
| <b>na.action</b>   | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                     |
| <b>...</b>         | further arguments to be passed to or from methods.                                                                                                                                                             |

## Details

The formula interface is only applicable for the 2-sample tests.

If only  $x$  is given, or if both  $x$  and  $y$  are given and paired is TRUE, a Wilcoxon signed rank test of the null that the distribution of  $x$  (in the one sample case) or of  $x - y$  (in the paired two sample case) is symmetric about  $\mu$  is performed.

Otherwise, if both  $x$  and  $y$  are given and paired is FALSE, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of  $x$  and  $y$  differ by a location shift of  $\mu$  and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that  $x$  is shifted to the right of  $y$ ).

By default (if exact is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally (if argument conf.int is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters  $x-y$  is computed. (The pseudomedian of a distribution  $F$  is the median of the distribution of  $(u+v)/2$ , where  $u$  and  $v$  are independent, each with distribution  $F$ . If  $F$  is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does **not** estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from  $x$  and a sample from  $y$ .

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but *not* the estimate (as the correction depends on the alternative).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

## Value

A list with class "htest" containing the following components:

|             |                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------|
| statistic   | the value of the test statistic with a name describing it.                                    |
| parameter   | the parameter(s) for the exact distribution of the test statistic.                            |
| p.value     | the p-value for the test.                                                                     |
| null.value  | the location parameter $\mu$ .                                                                |
| alternative | a character string describing the alternative hypothesis.                                     |
| method      | the type of test applied.                                                                     |
| data.name   | a character string giving the names of the data.                                              |
| conf.int    | a confidence interval for the location parameter. (Only present if argument conf.int = TRUE.) |
| estimate    | an estimate of the location parameter. (Only present if argument conf.int = TRUE.)            |

## Warning

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if exact = TRUE and one sample is large (several thousands or more).

## Note

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: R subtracts and S-PLUS does not, giving a value which is larger by  $m(m + 1)/2$  for a first sample of size  $m$ . (It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)

R's value can also be computed as the number of all pairs ( $x[i]$ ,  $y[j]$ ) for which  $y[j]$  is not greater than  $x[i]$ , the most common definition of the Mann-Whitney test.

```

**Wilcoxon***Distribution of the Wilcoxon Rank Sum Statistic***Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size  $m$  and  $n$ , respectively.

**Usage**

```
dwilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcox(nn, m, n)
```

**Arguments**

|                     |                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------|
| $x, q$              | vector of quantiles.                                                                                       |
| $p$                 | vector of probabilities.                                                                                   |
| $nn$                | number of observations. If $\text{length}(nn) > 1$ , the length is taken to be the number required.        |
| $m, n$              | numbers of observations in the first and second sample, respectively. Can be vectors of positive integers. |
| $\log, \log.p$      | logical; if TRUE, probabilities $p$ are given as $\log(p)$ .                                               |
| $\text{lower.tail}$ | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                      |

**Details**

This distribution is obtained as follows. Let  $x$  and  $y$  be two random, independent samples of size  $m$  and  $n$ . Then the Wilcoxon rank sum statistic is the number of all pairs  $(x[i], y[j])$  for which  $y[j]$  is not greater than  $x[i]$ . This statistic takes values between 0 and  $m * n$ , and its mean and variance are  $m * n / 2$  and  $m * n * (m + n + 1) / 12$ , respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

**Value**

`dwilcox` gives the density, `pwilcox` gives the distribution function, `qwilcox` gives the quantile function, and `rwilcox` generates random deviates.

The length of the result is determined by  $nn$  for `rwilcox`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than  $nn$  are recycled to the length of the result. Only the first elements of the logical parameters are used.

## Warning

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

## Note

S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see [wilcox.test](#) for details.

## Author(s)

Kurt Hornik

## Source

These are calculated via recursion, based on `cwilcox(k, m, n)`, the number of choices with statistic k from samples of size m and n, which is itself calculated recursively and the results cached. Then `dwilcox` and `pwilcox` sum appropriate values of `cwilcox`, and `qwilcox` is based on inversion.

`rwilcox` generates a random permutation of ranks and evaluates the statistic.

## See Also

[wilcox.test](#) to calculate the statistic from data, find p values and so on.

points(x, N*fx, cex = 2)

Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m = 4, n = 6),
 main = paste("Q-Q-Plot of empirical and theoretical quantiles",
 "Wilcoxon Statistic, (m=4, n=6)", sep = "\n"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels = tU, col = "red")
```

**window***Time Windows*

## Description

`window` is a generic function which extracts the subset of the object `x` observed between the times `start` and `end`. If a frequency is specified, the series is then re-sampled at the new frequency.

## Usage

```
window(x, ...)
S3 method for class ts
window(x, ...)
Default S3 method:
window(x, start = NULL, end = NULL,
 frequency = NULL, deltat = NULL, extend = FALSE, ...)

window(x, ...) <- value
S3 replacement method for class ts
window(x, start, end, frequency, deltat, ...) <- value
```

## Arguments

- `x` a time-series (or other object if not replacing values).
- `start` the start time of the period of interest.
- `end` the end time of the period of interest.
- `frequency, deltat` the new frequency can be specified by either (or both if they are consistent).
- `extend` logical. If true, the `start` and `end` values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.
- `...` further arguments passed to or from other methods.
- `value` replacement values.

## Details

The start and end times can be specified as for `ts`. If there is no observation at the new `start` or `end`, the immediately following (`start`) or preceding (`end`) observation time is used.

The replacement function has a method for `ts` objects, and is allowed to extend the series (with a warning). There is no default method.

## Value

The value depends on the method. `window.default` will return a vector or matrix with an appropriate `tsp` attribute.

`window.ts` differs from `window.default` only in ensuring the result is a `ts` object.

If `extend = TRUE` the series will be padded with NAs if needed.

window(presidents, deltat = 1) # All Qtr1s
window(presidents, start = c(1945,3), deltat = 1) # All Qtr3s
window(presidents, 1944, c(1979,2), extend = TRUE)

pres <- window(presidents, 1945, c(1949,4)) # values in the 1940s
window(pres, 1945.25, 1945.50) <- c(60, 70)
window(pres, 1944, 1944.75) <- 0 # will generate a warning
window(pres, c(1945,4), c(1949,4), frequency = 1) <- 85:89
pres
```

*xtabs*

*Cross Tabulation*

## Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

## Usage

```
xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE,
 na.action, exclude = c(NA, NaN), drop.unused.levels = FALSE)
```

## Arguments

- |           |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a <a href="#">formula</a> object with the cross-classifying variables (separated by +) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below. |
| data      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                                                                                                 |
| subset    | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                                                                                                                                                                                         |
| sparse    | logical specifying if the result should be a <i>sparse</i> matrix, i.e., inheriting from <a href="#">sparseMatrix</a> . Only works for two factors (since there are no higher-order sparse array classes yet).                                                                                                                                                                                                                                             |
| na.action | a function which indicates what should happen when the data contain NAs.                                                                                                                                                                                                                                                                                                                                                                                   |

**exclude** a vector of values to be excluded when forming the set of levels of the classifying factors.

**drop.unused.levels** a logical indicating whether to drop unused levels in the classifying factors. If this is FALSE and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.

## Details

There is a summary method for contingency table objects created by `table` or `xtabs(*, sparse = FALSE)`, which gives basic information and performs a chi-squared test for independence of factors (note that the function `chisq.test` currently only handles 2-d tables).

If a left hand side is given in `formula`, its entries are simply summed over the cells corresponding to the right hand side; this also works if the `lhs` does not give counts.

For variables in `formula` which are factors, `exclude` must be specified explicitly; the default exclusions will not be used.

## Value

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class `c("xtabs", "table")`, with a "call" attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class `dgTMatrix` from package **Matrix**.

## See Also

`table` for traditional cross-tabulation, and `as.data.frame.table` which is the inverse operation of `xtabs` (see the DF example below).

`sparseMatrix` on sparse matrices in package **Matrix**.

## Examples

```
esoph has the frequencies of cases and controls for all levels of
the variables agegp, alcgp, and tobgp.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
Now DF is a data frame with a grid of the factors and the counts
in variable Freq.
DF
Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
And for testing independence ...
summary(xtabs(Freq ~ ., DF))

Create a nice display for the warp break data.
warpbreaks$replicate <- rep(1:9, len = 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))
```

```
---- Sparse Examples ----

if(require("Matrix")) {
 ## similar to "nlme"s ergoStool :
 d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
 Subj = gl(9, 4, 36*4))
 print(xtabs(~ Type + Subj, data = d.ergo)) # 4 replicates each
 set.seed(15) # a subset of cases:
 print(xtabs(~ Type + Subj, data = d.ergo[sample(36, 10),], sparse = TRUE))

 ## Hypothetical two level setup:
 inner <- factor(sample(letters[1:25], 100, replace = TRUE))
 inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
 fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
 print(xtabs(~ inner + outer, fr, sparse = TRUE))
}
```

# Chapter 11

## The stats4 package

---

stats4-package

*Statistical Functions using S4 Classes*

---

### Description

Statistical Functions using S4 classes.

### Details

This package contains functions and classes for statistics using the [S version 4](#) class system.

The methods currently support maximum likelihood (function `mle()` returning class "`mle`"), including methods for `logLik` for use with [AIC](#).

### Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

---

coef-methods

*Methods for Function `coef` in Package **stats4***

---

### Description

Extract the coefficient vector from "`mle`" objects.

### Methods

`signature(object = "ANY")` Generic function: see [coef](#).

`signature(object = "mle")` Extract the full coefficient vector (including any fixed coefficients) from the fit.

`signature(object = "summary.mle")` Extract the coefficient vector and standard errors from the summary of the fit.

---

**confint-methods***Methods for Function confint in Package stats4*

---

**Description**

Generate confidence intervals

**Methods**

```
signature(object = "ANY") Generic function: see confint.
signature(object = "mle") First generate profile and then confidence intervals from the profile.
signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.
```

---

**logLik-methods***Methods for Function logLik in Package stats4*

---

**Description**

Extract the maximized log-likelihood from "mle" objects.

**Methods**

```
signature(object = "ANY") Generic function: see logLik.
signature(object = "mle") Extract log-likelihood from the fit.
```

**Note**

The `mle` method does not know about the number of observations unless `nobs` was specified on the call and so may not be suitable for use with [BIC](#).

---

**mle***Maximum Likelihood Estimation*

---

**Description**

Estimate parameters by the method of maximum likelihood.

**Usage**

```
mle(minuslogl, start = formals(minuslogl), method = "BFGS",
 fixed = list(), nobs, ...)
```

## Arguments

|           |                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------|
| minuslogl | Function to calculate negative log-likelihood.                                                    |
| start     | Named list. Initial values for optimizer.                                                         |
| method    | Optimization method to use. See <a href="#">optim</a> .                                           |
| fixed     | Named list. Parameter values to keep fixed during optimization.                                   |
| nobs      | optional integer: the number of observations, to be used for e.g. computing <a href="#">BIC</a> . |
| ...       | Further arguments to pass to <a href="#">optim</a> .                                              |

## Details

The [optim](#) optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum.

## Value

An object of class [mle-class](#).

## Note

Be careful to note that the argument is  $-\log L$  (not  $-2 \log L$ ). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

## See Also

[mle-class](#)

## Examples

```
Avoid printing to unwarranted accuracy
od <- options(digits = 5)
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)

Easy one-dimensional MLE:
nLL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))
For 1D, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
 method = "Brent", lower = 1, upper = 20)
stopifnot(nobs(fit0) == length(y))

This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
 if(ymax > 0 && xhalf > 0)
 -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
 else NA
}
(fit <- mle(ll, nobs = length(y)))
mle(ll, fixed = list(xhalf = 6))
alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
 -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, method = "L-BFGS-B", lower = rep(0, 2))
```

```

AIC(fit)
BIC(fit)

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal = FALSE)
confint(fit)

Use bounded optimization
The lower bounds are really > 0,
but we use >=0 to stress-test profiling
(fit2 <- mle(ll, method = "L-BFGS-B", lower = c(0, 0)))
plot(profile(fit2), absVal = FALSE)

a better parametrization:
ll3 <- function(lymax = log(15), lxhalf = log(6))
 -sum(stats::dpois(y, lambda = exp(lymax)/(1+x/exp(lxhalf)), log = TRUE))
(fit3 <- mle(ll3))
plot(profile(fit3), absVal = FALSE)
exp(confint(fit3))

options(od)

```

**mle-class***Class "mle" for Results of Maximum Likelihood Estimation***Description**

This class encapsulates results of a generic maximum likelihood procedure.

**Objects from the Class**

Objects can be created by calls of the form `new("mle", ...)`, but most often as the result of a call to `mle`.

**Slots**

- call:** Object of class "language". The call to `mle`.
- coef:** Object of class "numeric". Estimated parameters.
- fullcoef:** Object of class "numeric". Fixed and estimated parameters.
- vcov:** Object of class "matrix". Approximate variance-covariance matrix.
- min:** Object of class "numeric". Minimum value of objective function.
- details:** a "list", as returned from `optim`.
- minuslogl:** Object of class "function". The negative loglikelihood function.
- nobs:** "integer" of length one. The number of observations (often NA, when not set in call explicitly).
- method:** Object of class "character". The optimization method used.

## Methods

**confint** signature(object = "mle"): Confidence intervals from likelihood profiles.

**logLik** signature(object = "mle"): Extract maximized log-likelihood.

**profile** signature(fitted = "mle"): Likelihood profile generation.

**nobs** signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.

**show** signature(object = "mle"): Display object briefly.

**summary** signature(object = "mle"): Generate object summary.

**update** signature(object = "mle"): Update fit.

**vcov** signature(object = "mle"): Extract variance-covariance matrix.

## Description

Plot profile likelihoods for "mle" objects.

## Usage

```
S4 method for signature profile.mle,missing
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
 absVal = TRUE, ...)
```

## Arguments

|        |                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | an object of class "profile.mle"                                                                                                                          |
| levels | levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly. |
| conf   | a numeric vector of confidence levels for profile-based confidence intervals on the parameters.                                                           |
| nseg   | an integer value giving the number of segments to use in the spline interpolation of the profile t curves.                                                |
| absVal | a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.                      |
| ...    | other arguments to the plot function can be passed here.                                                                                                  |

## Methods

signature(x = "ANY", y = "ANY") Generic function: see [plot](#).

signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.

---

**profile-methods***Methods for Function profile in Package stats4*

---

**Description**

Profile likelihood for "mle" objects.

**Usage**

```
S4 method for signature mle
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
 zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
 trace = FALSE, ...)
```

**Arguments**

|          |                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------|
| fitted   | Object to be profiled                                                                                                       |
| which    | Optionally select subset of parameters to profile.                                                                          |
| maxsteps | Maximum number of steps to bracket zmax.                                                                                    |
| alpha    | Significance level corresponding to zmax, based on a Scheffe-style multiple testing interval. Ignored if zmax is specified. |
| zmax     | Cutoff for the profiled value of the signed root-likelihood.                                                                |
| del      | Initial stepsize on root-likelihood scale.                                                                                  |
| trace    | Logical. Print intermediate results.                                                                                        |
| ...      | Currently unused.                                                                                                           |

**Details**

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

**Value**

An object of class "profile.mle", see "profile.mle-class".

**Methods**

```
signature(fitted = "ANY") Generic function: see profile.
signature(fitted = "mle") Profile the likelihood in the vicinity of the optimum of an "mle"
object.
```

---

|                                |                                                                    |
|--------------------------------|--------------------------------------------------------------------|
| <code>profile.mle-class</code> | <i>Class "profile.mle"; Profiling information for "mle" object</i> |
|--------------------------------|--------------------------------------------------------------------|

---

## Description

Likelihood profiles along each parameter of likelihood function

## Objects from the Class

Objects can be created by calls of the form `new("profile.mle", ...)`, but most often by invoking `profile` on an "mle" object.

## Slots

**profile:** Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.

**summary:** Object of class "summary.mle". Summary of object being profiled.

## Methods

**confint** `signature(object = "profile.mle")`: Use `profile` to generate approximate confidence intervals for parameters.

**plot** `signature(x = "profile.mle", y = "missing")`: Plot profiles for each parameter.

## See Also

`mle`, `mle-class`, `summary.mle-class`

|---------------------------|------------------------------------------------------------------------|
| <code>show-methods</code> | <i>Methods for Function <code>show</code> in Package <b>stats4</b></i> |
|---------------------------|------------------------------------------------------------------------|

---

## Description

Show objects of classes `mle` and `summary.mle`

## Methods

`signature(object = "mle")` Print simple summary of `mle` object. Just the coefficients and the call.

`signature(object = "summary.mle")` Shows call, table of coefficients and standard errors, and  $-2 \log L$ .

---

**summary-methods***Methods for Function summary in Package stats4*

---

**Description**

Summarize objects

**Methods**

**signature(object = "ANY")** Generic function

**signature(object = "mle")** Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of  $-2 \log L$ .

---

**summary.mle-class***Class "summary.mle", Summary of "mle" Objects*

---

**Description**

Extract of "mle" object

**Objects from the Class**

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

**Slots**

**call:** Object of class "language" The call that generated the "mle" object.

**coef:** Object of class "matrix". Estimated coefficients and standard errors

**m2logL:** Object of class "numeric". Minus twice the log likelihood.

**Methods**

**show** `signature(object = "summary.mle")`: Pretty-prints object

**coef** `signature(object = "summary.mle")`: Extracts the contents of the `coef` slot

**See Also**

## update-methods

*Methods for Function update in Package stats4***Description**

Update "mle" objects.

**Usage**

```
S4 method for signature mle
update(object, ..., evaluate = TRUE)
```

**Arguments**

- |          |                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------|
| object   | An existing fit.                                                                                                 |
| ...      | Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name. |
| evaluate | If true evaluate the new call else return the call.                                                              |

**Methods**

- `signature(object = "ANY")` Generic function: see [update](#).
- `signature(object = "mle")` Update a fit.

**Examples**

```
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
 -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
```

## vcov-methods

*Methods for Function vcov in Package stats4***Description**

Extract the approximate variance-covariance matrix from "mle" objects.

**Methods**

- `signature(object = "ANY")` Generic function: see [vcov](#).
- `signature(object = "mle")` Extract the estimated variance-covariance matrix for the estimated parameters (if any).

# Chapter 12

## The `tcltk` package

---

`tcltk-package`

*Tcl/Tk Interface*

---

### Description

Interface and language bindings to Tcl/Tk GUI elements.

### Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See [TkWidgets](#) for a list of supported widgets, [TkWidgetcmds](#) for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use `ls("package:tcltk")`.

Note that Tk will not be initialized if there is no `DISPLAY` variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on `tcltk` in a session that does not actually use it (e.g. during installation).

### Author(s)

R Core Team

Maintainer: R Core Team <[R-core@r-project.org](mailto:R-core@r-project.org)>

---

`TclInterface`

*Low-level Tcl/Tk Interface*

---

### Description

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class `tclVar` and the C level interface to Tcl objects is accessed via objects of class `tclObj`.

**Usage**

```
.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init = "")
S3 method for class tclVar
as.character(x, ...)
S3 method for class tclVar
tclvalue(x)
S3 replacement method for class tclVar
tclvalue(x) <- value

tclArray()
S3 method for class tclArray
x[[...]]
S3 replacement method for class tclArray
x[[...]] <- value
S3 method for class tclArray
x$i
S3 replacement method for class tclArray
x$i <- value

S3 method for class tclArray
names(x)
S3 method for class tclArray
length(x)

tclObj(x)
tclObj(x) <- value
S3 method for class tclVar
tclObj(x)
S3 replacement method for class tclVar
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

S3 method for class tclObj
as.character(x, ...)
```

```

S3 method for class tclObj
as.integer(x, ...)
S3 method for class tclObj
as.double(x, ...)
S3 method for class tclObj
as.logical(x, ...)
S3 method for class tclObj
as.raw(x, ...)
S3 method for class tclObj
tclvalue(x)

Default S3 method:
tclvalue(x)
Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)

```

### Arguments

|         |                                                                                                                       |
|---------|-----------------------------------------------------------------------------------------------------------------------|
| objv    | a named vector of Tcl objects                                                                                         |
| win     | a window structure                                                                                                    |
| x       | an object                                                                                                             |
| i       | character or (unquoted) name                                                                                          |
| drop    | logical. Indicates whether a single-element vector should be made into a simple<br>Tcl object or a list of length one |
| value   | For tclvalue assignments, a character string. For tclObj assignments, an ob-<br>ject of class tclObj                  |
| ID      | a window ID                                                                                                           |
| parent  | a window which becomes the parent of the resulting window                                                             |
| path    | path to a directory containing Tcl packages                                                                           |
| package | a Tcl package name                                                                                                    |
| warn    | logical. Warn if not found?                                                                                           |
| ...     | Additional arguments. See below.                                                                                      |
| init    | initialization value                                                                                                  |

### Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level .Tcl sends a command as a text string to the Tcl interpreter and returns the result as an object of class tclObj (see below). A newer variant .Tcl.objv accepts arguments in the form of a named list of tclObj objects.

.Tcl.args converts an R argument list of tag = value pairs to the Tcl -option value style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value tag = NULL can be used. Most values are just converted to character mode and inserted in

the command string, but window objects are passed using their ID string, and callbacks are passed via the result of `.Tcl.callback`. Tags are converted to option flags simply by prepending a `-`

`.Tcl.args.objv` serves a similar purpose as `.Tcl.args` but produces a list of `tclObj` objects suitable for passing to `.Tcl.objv`. The names of the list are converted to Tcl option style internally by `.Tcl.objv`.

Callbacks can be either *atomic callbacks* handled by `.Tcl.callback` or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the break expression is translated directly to the Tcl counterpart. `.Tcl.callback` converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode "call" followed by an environment. The return value in the first case is of the form `R_call 0x408b94d4` in which the hexadecimal number is the memory address of the function. In the second case it will be of the form `R_call_lang 0x8a95904 0x819bfd0`. For expressions, a sequence of similar items is generated, separated by semicolons. `.Tcl.args` takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class `tkwin` which are lists containing a `ID` field and an `env` field which is an R environments, enclosed in the global environment. The value of the `ID` field is identical to the Tk window name. The `env` environment contains a `parent` variable and a `num.subwin` variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. `.TkRoot` is the top window with ID `".`; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The `parent` variable is undefined for `.TkRoot`.

`.Tk.ID` extracts the `ID` of a window, `.Tk.newwin` creates a new window environment with a given `ID` and `.Tk.subwin` creates a new window which is a sub-window of a given parent window.

`tkdestroy` destroys a window and also removes the reference to a window from its parent.

`is.tkwin` can be used to test whether a given object is a window environment.

`tclVar` creates a new Tcl variable and initializes it to `init`. An R object of class `tclVar` is created to represent it. Using `as.character` on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the `tclvalue` function, which can also occur on the left-hand side of assignments. If `tclvalue` is passed an argument which is not a `tclVar` object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by `tclVar` are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

`tclArray` creates a new Tcl array and initializes it to the empty array. An R object of class `tclArray` and inheriting from class `tclVar` is created to represent it. You can access elements of the Tcl array using indexing with `[]` or `$`, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index `i` refers to the element with the *name* `as.character(i)`. Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for `length` and `names`, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl's 'dual-ported' objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class `tclObj`. The string representation of such objects can be extracted (but not set) using `tclvalue` and conversion to vectors of mode "character", "double", "integer", "logical", and "raw" is performed using the standard coercion functions `as.character`, etc. Conversely, such vectors can be converted using `as.tclObj`. There is an ambiguity as to what should happen for length one vectors, controlled by the `drop` argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that `tclvalue` and `as.character` differ on an object whose string representation

has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of `tclread`, `tkgetOpenFile`, and similar functions. The `as.raw` method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a `tclVar` object is extracted using `tclObj(x)` which also allows an assignment form, in which the right hand side of the assignment is automatically converted using `as.tclObj`. There is a `print` method for `tclObj` objects; it prints `<Tcl>` followed by the string representation of the object. Notice that `as.character` on a `tclVar` object is the *name* of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`. The return value is a class "tclObj" object if it succeeds, or FALSE if it fails (when a warning is issued). To see the current search path as an R character vector, use

```
strsplit(tclvalue(auto_path), " ")[[1]]
```

### Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

### See Also

[TkWidgets](#), [TkCommands](#), [TkWidgetcmds](#).

[capabilities\("tcltk"\)](#) to see if Tcl/Tk support was compiled into this build of R.

### Examples

```
Not run:
These cannot be run by example() but should be OK when pasted
into an interactive R session with the tcltk package loaded
.Tcl("format \"%s\n\" \"Hello, World!\\n\"")
f <- function()cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzzy <- tclVar(7913)
tclvalue(xyzzy)
tclvalue(xyzzy) <- "foo"
as.character(xyzzy)
tcl("set", as.character(xyzzy))

top <- tkoplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all = TRUE)
ls(envir = .TkRoot$env, all = TRUE) # .Tcl.args put a callback ref in here

End(Not run)
```

|                |                                               |
|----------------|-----------------------------------------------|
| tclServiceMode | <i>Allow Tcl events to be serviced or not</i> |
|----------------|-----------------------------------------------|

## Description

This function controls or reports on the Tcl service mode, i.e. whether Tcl will respond to events.

## Usage

```
tclServiceMode(on = NULL)
```

## Arguments

on                   (logical) Whether event servicing is turned on.

## Details

If called with on == NULL (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

## Value

The value of the Tcl service mode before the call.

## Examples

```
see demo(tkcanvas) for an example
Not run:
oldmode <- tclServiceMode(FALSE)
Do some work to create a nice picture.
Nothing will be displayed until...
tclServiceMode(oldmode)

End(Not run)
another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

|            |                               |
|------------|-------------------------------|
| TkCommands | <i>Tk non-widget commands</i> |
|------------|-------------------------------|

## Description

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.

**Usage**

```
tcl(...)
tktitle(x)

tktitle(x) <- value

tkbell(...)
tkbind(...)
tkbindtags(...)
tkfocus(...)
tklower(...)
tkraise(...)

tkclipboard.append(...)
tkclipboard.clear(...)

tkevent.add(...)
tkevent.delete(...)
tkevent.generate(...)
tkevent.info(...)

tkfont.actual(...)
tkfont.configure(...)
tkfont.create(...)
tkfont.delete(...)
tkfont.families(...)
tkfont.measure(...)
tkfont.metrics(...)
tkfont.names(...)

tkgrab(...)
tkgrab.current(...)
tkgrab.release(...)
tkgrab.set(...)
tkgrab.status(...)

tkimage.cget(...)
tkimage.configure(...)
tkimage.create(...)
tkimage.names(...)

NB: some widgets also have a selection.clear command,
hence the "X".

tkXselection.clear(...)
tkXselection.get(...)
tkXselection.handle(...)
tkXselection.own(...)

tkwait.variable(...)
tkwait.visibility(...)
tkwait.window(...)
```

```
winfo actually has a large number of subcommands,
but its rarely used,
so use tkwinfo("atom", ...) etc. instead.

tkwinfo(...)

Window manager interface

tkwm.aspect(...)
tkwm.client(...)
tkwm.colormapwindows(...)
tkwm.command(...)
tkwm.deiconify(...)
tkwm.focusmodel(...)
tkwm.frame(...)
tkwm.geometry(...)
tkwm.grid(...)
tkwm.group(...)
tkwm.iconbitmap(...)
tkwm.iconify(...)
tkwm.iconmask(...)
tkwm.iconname(...)
tkwm.iconposition(...)
tkwm.iconwindow(...)
tkwm.maxsize(...)
tkwm.minsize(...)
tkwm.overrideredirect(...)
tkwm.positionfrom(...)
tkwm.protocol(...)
tkwm.resizable(...)
tkwm.sizefrom(...)
tkwm.state(...)
tkwm.title(...)
tkwm.transient(...)
tkwm.withdraw(...)

Geometry managers

tkgrid(...)
tkgrid.bbox(...)
tkgrid.columnconfigure(...)
tkgrid.configure(...)
tkgrid.forget(...)
tkgrid.info(...)
tkgrid.location(...)
tkgrid.propagate(...)
tkgrid.rowconfigure(...)
tkgrid.remove(...)
tkgrid.size(...)
tkgrid.slaves(...)
```

```

tkpack(...)
tkpack.configure(...)
tkpack.forget(...)
tkpack.info(...)
tkpack.propagate(...)
tkpack.slaves(...)

tkplace(...)
tkplace.configure(...)
tkplace.forget(...)
tkplace.info(...)
tkplace.slaves(...)

Standard dialogs
tkgetOpenFile(...)
tkgetSaveFile(...)
tkchooseDirectory(...)
tkmessageBox(...)
tkdialog(...)
tkpopup(...)

```

```

File handling functions
tclfile.tail(...)
tclfile.dir(...)
tclopen(...)
tclclosse(...)
tclputs(...)
tclread(...)

```

## Arguments

|       |                                                            |
|-------|------------------------------------------------------------|
| x     | A window object                                            |
| value | For <code>tkttitle</code> assignments, a character string. |
| ...   | Handled via <code>.Tcl.args</code>                         |

## Details

`tcl` provides a generic interface to calling any Tk or Tcl command by simply running `.Tcl.args.objv` on the argument list and passing the result to `.Tcl.objv`. Most of the other commands simply call `tcl` with a particular first argument and sometimes also a second argument giving the subcommand.

`tkttitle` and its assignment form provides an alternate interface to Tk's `wm title`.

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like `pack` `configure` are converted to function names like `tkpack.configure`, and Tcl subcommands are like `tclfile.dir`.

## See Also

[TclInterface](#), [TkWidgets](#), [TkWidgetcmds](#)

## Examples

```
Not run:
These cannot be run by examples() but should be OK when pasted
into an interactive R session with the tcltk package loaded

tt <- tkoplevel()
tkpack(l1 <- tklabel(tt, text = "Heave"), l2<- tklabel(tt, text = "Ho"))
tkpack.configure(l1, side = "left")

Try stretching the window and then

tkdestroy(tt)

End(Not run)
```

**tkpager**

*Page file using Tk text widget*

## Description

This plugs into `file.show`, showing files in separate windows.

## Usage

```
tkpager(file, header, title, delete.file)
```

## Arguments

|                          |                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------|
| <code>file</code>        | character vector containing the names of the files to be displayed                                  |
| <code>header</code>      | headers to use for each file                                                                        |
| <code>title</code>       | common title to use for the window(s). Pasted together with the header to form actual window title. |
| <code>delete.file</code> | logical. Should file(s) be deleted after display?                                                   |

## Note

The "\b\_" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

## See Also

[file.show](#)

---

**tkProgressBar** *Progress Bars via Tk*

---

**Description**

Put up a Tk progress bar widget.

**Usage**

```
tkProgressBar(title = "R progress bar", label = "",
 min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
S3 method for class tkProgressBar
close(con, ...)
```

**Arguments**

**title, label** character strings, giving the window title and the label on the dialog box respectively.  
**min, max** (finite) numeric values for the extremes of the progress bar.  
**initial, value** initial or new value for the progress bar.  
**width** the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).  
**pb, con** an object of class "tkProgressBar".  
**...** for consistency with the generic.

**Details**

**tkProgressBar** will display a widget containing a label and progress bar.

**setTkProgressBar** will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (**NA**) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with.

This will use the **ttk::progressbar** widget for Tk version 8.5 or later, otherwise R's copy of BWidget's **progressbar**.

**Value**

For **tkProgressBar** an object of class "tkProgressBar".

For **getTkProgressBar** and **setTkProgressBar**, a length-one numeric vector giving the previous value (invisibly for **setTkProgressBar**).

**See Also**

[txtProgressBar](#)

## Examples

```
pb <- tkProgressBar("test progress bar", "Some information in %",
 0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
 Sys.sleep(0.1)
 info <- sprintf("%d% done", round(i))
 setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

**tkStartGUI**

*Tcl/Tk GUI startup*

## Description

Starts up the Tcl/Tk GUI

## Usage

```
tkStartGUI()
```

## Details

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

## Note

`tkStartGUI()` saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = .GUIenv)`.

## Author(s)

**TkWidgetcmds**

*Tk widget commands*

## Description

These functions interface to Tk widget commands.

**Usage**

```
tkactivate(widget, ...)
tkadd(widget, ...)
tkaddtag(widget, ...)
tkbbox(widget, ...)

tkyview.scroll(widget, ...)

```

### Arguments

|        |                                    |
|--------|------------------------------------|
| widget | The widget this applies to         |
| ...    | Handled via <code>.Tcl.args</code> |

### Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like `a.b selection clear` are converted to function names like `tkselection.clear` and the widget is given as the first argument.

**See Also**

[TclInterface](#), [TkWidgets](#), [TkCommands](#)

**Examples**

```
Not run:
These cannot be run by examples() but should be OK when pasted
into an interactive R session with the tcltk package loaded

tt <- tkoplevel()
tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)")

callback function
eval.txt <- function()
 eval(parse(text = tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(button.w <- tkbutton(tt, text = "Submit", command = eval.txt))

Try pressing the button, edit the text and when finished:

tkdestroy(tt)

End(Not run)
```

---

TkWidgets

*Tk widgets*

---

**Description**

Create Tk widgets and associated R objects.

**Usage**

```
tkwidget(parent, type, ...)

tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckbox(parent, ...)
tkentry(parent, ...)
ttkentry(parent, ...)
tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tkmenu(parent, ...)
tkmenubutton(parent, ...)
tkmessage(parent, ...)
tkradiobutton(parent, ...)
tkscale(parent, ...)
tkscrollbar(parent, ...)
tktext(parent, ...)
tktoplevel(parent = .TkRoot, ...)
```

```

ttkbutton(parent, ...)
ttkcheckbutton(parent, ...)
ttkcombobox(parent, ...)
ttkframe(parent, ...)
ttkimage(parent, ...)
ttklabellframe(parent, ...)
ttkmenubutton(parent, ...)
ttknotebook(parent, ...)
ttkpanedwindow(parent, ...)
ttkprogressbar(parent, ...)
ttkradiobutton(parent, ...)
ttkscrollbar(parent, ...)
ttkseparator(parent, ...)
ttksizegrip(parent, ...)
ttktreeview(parent, ...)

```

## Arguments

|        |                                               |
|--------|-----------------------------------------------|
| parent | Parent of widget window.                      |
| type   | string describing the type of widget desired. |
| ...    | handled via <a href="#">.Tcl.args</a> .       |

## Details

These functions create Tk widgets. `tkwidget` creates a widget of a given type, the others simply call `tkwidget` with the respective type argument.

The functions starting `ttk` are for the themed widget set for Tk 8.5 or later. A tutorial can be found at <http://www.tkdocs.com>.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

## See Also

[TclInterface](#), [TkCommands](#), [TkWidgetcmds](#)

## Examples

```

Not run:
These cannot be run by examples() but should be OK when pasted
into an interactive R session with the tcltk package loaded

tt <- tkoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- tkbutton(tt, text = "Push",
 command = function()cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
 # see Tk-commands

Push the button and then...

tkdestroy(tt)

```

```
test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
 # make use of themed widgets
 # list themes
 as.character(tcl("ttk::style", "theme", "names"))
 # select a theme -- here pre-XP windows
 tcl("ttk::style", "theme use", "winnative")
} else {
 # use Tk 8.0 widgets
}

End(Not run)
```

---

tk\_choose.dir      *Choose a Folder Interactively*

---

## Description

Use a Tk widget to choose a directory interactively.

## Usage

```
tk_choose.dir(default = "", caption = "Select directory")
```

## Arguments

|         |                                      |
|---------|--------------------------------------|
| default | which directory to show initially.   |
| caption | the caption on the selection dialog. |

## Value

A length-one character vector, character NA if ‘Cancel’ was selected.

## See Also

[tk\\_choose.files](#)

## Examples

```
Not run:
tk_choose.dir(getwd(), "Choose a suitable folder")

End(Not run)
```

`tk_choose.files`      *Choose a List of Files Interactively*

## Description

Use a Tk file dialog to choose a list of zero or more files interactively.

## Usage

```
tk_choose.files(default = "", caption = "Select files",
 multi = TRUE, filters = NULL, index = 1)
```

## Arguments

|                      |                                                  |
|----------------------|--------------------------------------------------|
| <code>default</code> | which filename to show initially.                |
| <code>caption</code> | the caption on the file selection dialog.        |
| <code>multi</code>   | whether to allow multiple files to be selected.  |
| <code>filters</code> | two-column character matrix of filename filters. |
| <code>index</code>   | unused.                                          |

## Details

Unlike [file.choose](#), `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas [file.choose](#) would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "\*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

## Value

A character vector giving zero or more file paths.

## Note

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

## See Also

[file.choose](#), [tk\\_choose.dir](#)

## Examples

```
Filters <- matrix(c("R code", ".R", "R code", ".s",
 "Text", ".txt", "All files", "*"),
 4, 2, byrow = TRUE)
Filters
if(interactive()) tk_choose.files(filter = Filters)
```

---

`tk_messageBox`*Tk Message Box*

---

### Description

An implementation of a generic message box using Tk

### Usage

```
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",
 "retrycancel", "aburtrycancel"),
 message, caption = "", default = "", ...)
```

### Arguments

|         |                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------|
| type    | character. The type of dialog box. It will have the buttons implied by its name.                         |
| message | character. The information field of the dialog box.                                                      |
| caption | the caption on the widget displayed.                                                                     |
| default | character. The name of the button to be used as the default.                                             |
| ...     | additional named arguments to be passed to the Tk function of this name. An example is icon = "warning". |

### Value

A character string giving the name of the button pressed.

### See Also

[tkmessageBox](#) for a ‘raw’ interface.

---

`tk_select.list`*Select Items from a List*

---

### Description

Select item(s) from a character vector using a Tk listbox.

### Usage

```
tk_select.list(choices, preselect = NULL, multiple = FALSE,
 title = NULL)
```

### Arguments

|           |                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| choices   | a character vector of items.                                                                                          |
| preselect | a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| multiple  | logical: can more than one item be selected?                                                                          |
| title     | optional character string for window title, or NULL for no title.                                                     |

**Details**

This is a version of [select.list](#) implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is *modal*, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

**Value**

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

**See Also**

[select.list](#) (a text version except on Windows and the OS X GUI), [menu](#) (whose `graphics = TRUE` mode uses this on most Unix-alikes).

# Chapter 13

## The tools package

---

tools-package

*Tools for Package Development*

---

### Description

Tools for package development, administration and documentation.

### Details

This package contains tools for manipulating R packages and their documentation.

For a complete list of functions, use `library(help = "tools")`.

### Author(s)

Kurt Hornik and Friedrich Leisch

Maintainer: R Core Team <[R-core@r-project.org](mailto:R-core@r-project.org)>

---

.print.via.format

*Printing Utilities*

---

### Description

`.print.via.format` is a “prototype” `print()` method, useful, at least as a start, by a simple

```
print.<myS3class> <- .print.via.format
```

### Usage

```
.print.via.format(x, ...)
```

### Arguments

- x object to be printed.
- ... optional further arguments, passed to `format`.

**Value**

`x`, invisibly (by `invisible()`), as `print` methods should.

**See Also**

The `print` generic; its default method `print.default` (used for many basic implicit classes such as "numeric", "character" and `arrays` of them, `lists` etc).

**Examples**

```
The function is simply defined as
function (x, ...) {
 writeLines(format(x, ...))
 invisible(x)
}

is used for simple print methods in R, and as prototype for new methods.
```

`add_datalist`

*Add a ‘datalist’ File to a Package*

**Description**

The `data()` command with no arguments lists all the datasets available via `data` in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by a supplying ‘`data/datalist`’ file.

**Usage**

```
add_datalist(pkgpath, force = FALSE)
```

**Arguments**

|                      |                                                                               |
|----------------------|-------------------------------------------------------------------------------|
| <code>pkgpath</code> | The path to a (source) package.                                               |
| <code>force</code>   | logical: can an existing ‘ <code>data/datalist</code> ’ file be over-written? |

**Details**

R CMD build will call this function to add a data list to packages with 1MB or more of data.

It is also helpful to give a ‘`data/datalist`’ file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).

**See Also**

`data`.

The ‘Writing R Extensions’ manual.

---

|                 |                                   |
|-----------------|-----------------------------------|
| assertCondition | <i>Asserting Error Conditions</i> |
|-----------------|-----------------------------------|

---

## Description

When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

## Usage

```
assertError(expr, verbose = FALSE)
assertWarning(expr, verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)
```

## Arguments

|             |                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| expr        | an unevaluated R expression which will be evaluated via <code>tryCatch(expr, ...)</code> .                                                                                                                                                                                                                                                            |
| ...         | <code>character</code> strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.                                                                                                                 |
| .exprString | The string to be printed corresponding to expr. By default, the actual expr will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If <code>assertCondition()</code> is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version. |
| verbose     | If TRUE, a message is printed when the condition is satisfied.                                                                                                                                                                                                                                                                                        |

## Details

`assertCondition()` uses the general condition mechanism to check all the conditions generated in evaluating expr. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.

`assertError()` is a convenience function for asserting errors; it calls `assertCondition()`.

`assertWarning()` asserts that a warning will be signalled, but *not* an error, whereas `assertCondition(expr, "warning")` will be satisfied even if an error follows the warning. See the examples.

## Value

If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See `conditionMessage` for the interpretation of these objects. Note that *all* conditions signalled during the evaluation are returned, whether or not they were among the requirements.

## Author(s)

John Chambers and Martin Maechler

**See Also**

[stop](#), [warning](#); [signalCondition](#), [tryCatch](#).

**Examples**

```
assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4,3))

assertCondition(""~-1) # ok, any condition would satisfy this

try(assertCondition(sqrt(2), "warning"))
.. Failed to get warning in evaluating sqrt(2)
 assertCondition(sqrt("abc"), "error") # ok
try(assertCondition(sqrt("abc"), "warning"))# -> error: had no warning
 assertCondition(sqrt("abc"), "error")
identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try(assertCondition(matrix(1:8, 4,3), "error"))
.. Failed to get expected error

either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4, 3), "warning") # OK

when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
 assertCondition(ff(), "warning")
but assertWarning does not allow an error to follow
try(assertWarning(ff()))
 assertCondition(ff(), "error") # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

assert that assertC..() does not assert [and use *one* argument only]
assertCondition(assertCondition(sqrt(2), "warning"))
assertCondition(assertCondition(sqrt("abc"), "warning"), "error")
assertCondition(assertCondition(matrix(1:8, 4,3), "error"),
 "error")
```

**bibstyle**

*Select or define a bibliography style.*

**Description**

This function defines and registers styles for rendering [bibentry](#) objects into ‘Rd’ format, for later conversion to text, HTML, etc.

**Usage**

```
bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)
```

## Arguments

|                       |                                                                         |
|-----------------------|-------------------------------------------------------------------------|
| <code>style</code>    | A character string naming the style.                                    |
| <code>envir</code>    | (optional) An environment holding the functions to implement the style. |
| <code>...</code>      | Named arguments to add to the environment.                              |
| <code>.init</code>    | Whether to initialize the environment from the default style "JSS".     |
| <code>.default</code> | Whether to set the specified style as the default style.                |
| <code>all</code>      | Whether to return the names of all registered styles.                   |

## Details

Rendering of `bibentry` objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the '`jss.bst`' style used by the *Journal of Statistical Software*.) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify `style` and some named entries via `....` (Modifying the default "JSS" style is discouraged.) Setting `style` to `NULL` or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by `bibentry` as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`, `formatIncollection`, `formatInProceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and `formatUnpublished`. Each of these takes one argument, a single `unclass`'ed entry from the `bibentry` vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. `sortKeys`, a function to produce a sort key to sort the entries, is passed the original `bibentry` vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function `cite` should have the same argument list as `utils::cite`, and should produce a citation to be used in text.

The `format` method for "bibentry" objects adds a field named ".index" to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn't use numbers, it includes a `fmtPrefix()` stub function that may be used to display them. See the example below.

## Value

`bibstyle` returns the environment which has been selected or created.

`getBibstyle` returns the name of the default style, or all style names.

## Author(s)

Duncan Murdoch

## See Also

`bibentry`

## Examples

```

refs <-

 c(bibentry(bibtype = "manual",

 title = "R: A Language and Environment for Statistical Computing",

 author = person("R Core Team"),

 organization = "R Foundation for Statistical Computing",

 address = "Vienna, Austria",

 year = 2013,

 title = "An Analysis of Transformations",

 journal = "Journal of the Royal Statistical Society, Series B",

 volume = 26,

 pages = "211-252"))

bibstyle("unsorted", sortKeys = function(refs) seq_along(refs),

 fmtPrefix = function(paper) paste0("[", paper$.index, "]"),

 .init = TRUE)
print(refs, .bibstyle = "unsorted")

```

## Description

Run [Sweave](#) (or other custom weave function) and [texi2dvi](#) on all vignettes of a package.

## Usage

```

buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE,

 clean = TRUE, tangle = FALSE)

pkgVignettes(package, dir, subdirs = NULL, lib.loc = NULL,

 output = FALSE, source = FALSE, check = FALSE)

```

## Arguments

|         |                                                                                                                                                                                                    |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. If given, Sweave files are searched in subdirectory ‘doc’.                                                                                         |
| dir     | a character string specifying the path to a package’s root source directory. This subdirectory ‘vignettes’ (or if it does not exist ‘inst/doc’) is searched for Sweave files.                      |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |
| quiet   | logical. Weave and run <a href="#">texi2pdf</a> in quiet mode.                                                                                                                                     |
| clean   | Remove all files generated by the build, even if there were copies there before.                                                                                                                   |
| tangle  | logical. Do tangling as well as weaving.                                                                                                                                                           |

|         |                                                                                                                                                                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subdirs | a character vector of subdirectories of <code>dir</code> in which to look for vignettes. Ignored if package is used.                                                                                                                                     |
| output  | logical. If TRUE, the output filename for each vignette in the result.                                                                                                                                                                                   |
| source  | logical. If TRUE, include the tangled output filename for each vignette in the result.                                                                                                                                                                   |
| check   | logical. If TRUE, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines. |

## Details

`buildVignettes` is used by R CMD build and R CMD check to (re-)build vignette PDFs from their (typically Sweave) sources.

## Value

`buildVignettes` is called for its side effect of creating the PDF versions of all vignettes, and if `tangle = TRUE`, extracting the R code.

`pkgVignettes` returns an object of class "pkgVignettes" if a vignette directory is found, otherwise NULL.

## Description

`charset_to_Unicode` is a matrix of Unicode points with columns for the common 8-bit encodings. `Adobe_glyphs` is a data frame which gives Adobe glyph names for Unicode points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

## Usage

```
charset_to_Unicode
Adobe_glyphs
```

## Details

`charset_to_Unicode` is an integer matrix of class c("noquote", "hexmode") so prints in hexadecimal. The mappings are those used by `libiconv`: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

`Adobe_glyphs` include all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode point and within a point alphabetically on the glyph (there can be more than one name for a Unicode point). The data are in the file '`R_HOME/share/encodings/Adobe_glyphlist`'.

## Source

<http://partners.adobe.com/public/developer/en/opentype/glyphlist.txt>

## Examples

```
find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Uncode[, "ISOLatin2"]
aUnicode <- as.numeric(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")
```

checkFF

*Check Foreign Function Calls*

## Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a "[NativeSymbolInfo](#)" first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

## Usage

```
checkFF(package, dir, file, lib.loc = NULL,
 verbose = getOption("verbose"))
```

## Arguments

|                      |                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package. If given, the installed R code of the package is checked.                                                                                                                                   |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'R' (for R code). Only used if <code>package</code> is not given.                                                         |
| <code>file</code>    | the name of a file containing R code to be checked. Used if neither <code>package</code> nor <code>dir</code> are given.                                                                                                                    |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> . |
| <code>verbose</code> | a logical. If <code>TRUE</code> , additional diagnostics are printed (and the result is returned invisibly).                                                                                                                                |

## Details

Note that we can only check if the `name` argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.

This checks that calls with PACKAGE specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the ‘DESCRIPTION’ file).

### Value

An object of class "checkFF".

There are `format` and `print` methods to display the information contained in such objects.

### See Also

[.C](#), [.Fortran](#); [Foreign](#).

### Examples

```
order is pretty much random
checkFF(package = "stats", verbose = TRUE)
```

---

checkMD5sums

*Check and Create MD5 Checksum Files*

---

### Description

`checkMD5sums` checks the files against a file ‘MD5’.

### Usage

```
checkMD5sums(package, dir)
```

### Arguments

|         |                                                              |
|---------|--------------------------------------------------------------|
| package | the name of an installed package                             |
| dir     | the path to the top-level directory of an installed package. |

### Details

The file ‘MD5’ which is created is in a format which can be checked by `md5sum -c MD5` if a suitable command-line version of `md5sum` is available. (For Windows, one is supplied in the bundle at <http://www.murdoch-sutherland.com/Rtools>.)

If `dir` is missing, an installed package of name `package` is searched for.

The private function `tools:::installMD5sums` is used to create MD5 files in the Windows build.

### Value

`checkMD5sums` returns a logical, NA if there is no ‘MD5’ file to be checked.

### See Also

[md5sum](#)

---

checkPoFiles*Check translation files for inconsistent format strings.*

---

**Description**

These functions compare formats embedded in English messages with translated strings to check for consistency. `checkPoFile` checks one file, while `checkPoFiles` checks all files for a specified language.

**Usage**

```
checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")
```

**Arguments**

|                           |                                                                          |
|---------------------------|--------------------------------------------------------------------------|
| <code>f</code>            | a character string giving a single filepath.                             |
| <code>strictPlural</code> | whether to compare formats of singular and plural forms in a strict way. |
| <code>language</code>     | a character string giving a language code.                               |
| <code>dir</code>          | a path to a directory in which to check files.                           |

**Details**

Part of R's internationalization depends on translations of messages in '.po' files. In these files an 'English' message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R `sprintf` and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely c, u, p, n. It is allowed in C's `sprintf()` function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the `strictPlural` argument is TRUE, then argument lists must agree exactly between singular and plural forms of messages; if FALSE, then translations only need to match one or the other of the two forms. When `checkPoFiles` calls `checkPoFile`, the `strictPlural` argument is set to TRUE for files with names starting 'R-', and to FALSE otherwise.

Items marked as 'fuzzy' in the '.po' file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g. the wide percent sign "\uFF05"). Such signs will not be recognized as format specifiers, and are likely to be errors.

**Value**

Both functions return an object of S3 class "check\_po\_files". A print method is defined for this class to display a report on the differences.

**Author(s)**

Duncan Murdoch

**References**

See the GNU gettext manual for the ‘.po’ file format:  
<http://www.gnu.org/software/gettext/manual/gettext.html>.

**See Also**[xgettext](#), [sprintf](#)**Examples**

```
Not run:
checkPoFiles("de", "/path/to/R/src/directory")

End(Not run)
```

---

checkRd*Check an Rd Object***Description**

Check an help file or the output of the [parse\\_Rd](#) function.

**Usage**

```
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
 unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

**Arguments**

|           |                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| Rd        | a filename or Rd object to use as input.                                                                                 |
| defines   | string(s) to use in #ifdef tests.                                                                                        |
| stages    | at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.                  |
| unknownOK | unrecognized macros are treated as errors if FALSE, otherwise warnings.                                                  |
| listOK    | unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if FALSE, otherwise warnings. |
| ...       | additional parameters to pass to <a href="#">parse_Rd</a> when Rd is a filename. One that is often useful is encoding.   |
| def_enc   | logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?                               |

## Details

checkRd performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use [parse\\_Rd](#) to parse it before applying the checks. If so, warnings from [parse\\_Rd](#) are collected, together with those from the internal function [prepare\\_Rd](#), which does the #ifdef and \Sexpr processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through [prepare\\_Rd](#), but it may already have been (and installed Rd objects have).

Warnings are given a ‘level’: those from [prepare\\_Rd](#) have level 0. These include

- All text must be in a section
- Only one *tag name* section is allowed: the first will be used
- Section *name* is unrecognized and will be dropped
- Dropping empty section *name*

checkRd itself can show

- 7 Tag *tag name* not recognized
- 7 \tabular format must be simple text
- 7 Unrecognized \tabular format: ...
- 7 Only *n* columns allowed in this table
- 7 Must have a *tag name*
- 7 Only one *tag name* is allowed
- 7 Tag *tag name* must not be empty
- 7 \docType must be plain text
- 5 Tag \method is only valid in \usage
- 5 Tag \dontrun is only valid in \examples
- 5 Tag *tag name* is invalid in a *block name* block
- 5 Title of \section must be non-empty plain text
- 5 \title content must be plain text
- 3 Empty section *tag name*
- 3 \synopsis will be removed in R 3.1.0
- 1 Non-ASCII contents without declared encoding
- 1 Non-ASCII contents in second part of \enc
- 3 Tag ... is not valid in a code block
- 3 Apparent non-ASCII contents without declared encoding
- 3 Apparent non-ASCII contents in second part of \enc
- 3 Unnecessary braces at ...
- 3 \method not valid outside a code block

and variations with \method replaced by \S3method or \S4method.

Note that both [prepare\\_Rd](#) and [checkRd](#) have tests for an empty section: that in [checkRd](#) is stricter (essentially that nothing is output).

## Value

This may fail through an R error, but otherwise warnings are collected as returned as an object of class "checkRd", a character vector of messages. This class has a [print](#) method which only

prints unique messages, and has argument `minlevel` that can be used to select only more serious messages. (This is set to `-1` in R CMD check.)

Possible fatal errors are those from running the parser (e.g. a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding) or from `prepare_Rd` (multiple \Rdversion declarations, invalid \encoding or \docType or \name sections, and missing or duplicate \name or \title sections).

### See Also

[parse\\_Rd](#), [Rd2HTML](#).

---

checkRdaFiles

*Report on Details of Saved Images or Re-saves them*

---

### Description

This reports for each of the files produced by `save` the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).

Usually such files have extension ‘.rda’ or ‘.RData’, hence the name of the function.

### Usage

```
checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),
 compression_level)
```

### Arguments

`paths` A character vector of paths to `save` files. If this specifies a single directory, it is taken to refer to all ‘.rda’ and ‘.RData’ files in that directory.  
`compress, compression_level`  
type and level of compression: see [save](#).

### Details

`compress = "auto"` asks R to choose the compression and ignores `compression_level`. It will try “gzip”, “bzip2” and if the “gzip” compressed size is over 10Kb, “xz” and choose the smallest compressed file (but with a 10% bias towards “gzip”). This can be slow.

### Value

For `checkRdaFiles`, a data frame with rows names `paths` and columns

`size` numeric: file size in bytes, NA if the file does not exist.  
`ASCII` logical: true for `save(ASCII = TRUE)`, NA if the format is not that of an R save file.

|          |                                                                                                                                                                 |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| compress | character: type of compression. One of "gzip", "bzip2", "xz", "none" or "unknown" (which means that if this is an R save file it is from a later version of R). |
| version  | integer: the version of the save – usually 2 but 1 for very old files, and NA for other files.                                                                  |

## Examples

```
Not run:
from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res$size > 1e4 & res$compress == "none")
res[bad,]

End(Not run)
```

## Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

## Usage

```
checkTnF(package, dir, file, lib.loc = NULL)
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                            |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.                                                                                                |
| dir     | a character string specifying the path to a package's root source directory. This must contain the subdirectory 'R' (for R code), and should also contain 'man' (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked. |
| file    | the name of a file containing R code to be checked. Used if neither package nor dir are given.                                                                                                                                                                                                             |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                                                         |

### Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a print method for nicely displaying the information contained in such objects.

---

|                |                                |
|----------------|--------------------------------|
| checkVignettes | <i>Check Package Vignettes</i> |
|----------------|--------------------------------|

---

### Description

Check all [Sweave](#) files of a package by running [Sweave](#) and/or [Stangle](#) on them. All R source code files found after the tangling step are [sourced](#) to check whether all code can be executed without errors.

### Usage

```
checkVignettes(package, dir, lib.loc = NULL,
 tangle = TRUE, weave = TRUE, latex = FALSE,
 workdir = c("tmp", "src", "cur"),
 keepfiles = FALSE)
```

### Arguments

|           |                                                                                                                                                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package   | a character string naming an installed package. If given, Sweave files are searched in subdirectory ‘doc’.                                                                                                                                                            |
| dir       | a character string specifying the path to a package’s root source directory. This subdirectory ‘inst/doc’ is searched for Sweave files.                                                                                                                               |
| lib.loc   | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                    |
| tangle    | Perform a tangle and <a href="#">source</a> the extracted code?                                                                                                                                                                                                       |
| weave     | Perform a weave?                                                                                                                                                                                                                                                      |
| latex     | logical: if weave and latex are TRUE and there is no ‘Makefile’ in the vignettes directory, run the weaved files through pdflatex.                                                                                                                                    |
| workdir   | Directory used as working directory while checking the vignettes. If "tmp" then a temporary directory is created, this is the default. If "src" then the directory containing the vignettes itself is used, if "cur" then the current working directory of R is used. |
| keepfiles | Delete files in the temporary directory? This option is ignored when workdir != "tmp".                                                                                                                                                                                |

## Details

A ‘vignette’ is a file in the package’s ‘inst/doc’ directory with extension ‘.Rnw’ (preferred), ‘.Snw’, ‘.Rtex’ or ‘.Stex’ (and lower-case versions are also accepted).

If `tangle` is true, this function runs `Stangle` to produce (one or more) R code files from each vignette, then sources each code file in turn.

If `weave` is true, the vignettes are run through `Sweave`, which will produce a ‘.tex’ file for each vignette. If `latex` is also true, `texi2pdf` is run on the ‘.tex’ files from those vignettes which did not give errors in the previous steps.

## Value

An object of class “`checkVignettes`”, which is a list with the error messages found during the tangle, source, weave and latex steps. There is a `print` method for displaying the information contained in such objects.

## Note

Prior to R 2.13.0 this was the code used by R CMD `check`, but the latter is now more careful, running the code for each vignette in a separate R session.

*check\_packages\_in\_dir Check Source Packages and Their Reverse Dependencies*

## Description

Check source packages in a given directory, optionally with their reverse dependencies.

## Usage

```
check_packages_in_dir(dir,
 check_args = character(),
 check_args_db = list(),
 reverse = NULL,
 check_env = character(),
 xvfb = FALSE,
 Ncpus = getOption("Ncpus", 1L),
 clean = TRUE,
 ...)

summarize_check_packages_in_dir_results(dir, all = TRUE)
summarize_check_packages_in_dir_timings(dir, all = FALSE,
 full = FALSE)
summarize_check_packages_in_dir_depends(dir, all = FALSE)
```

## Arguments

- |                         |                                                                                                                                                                                                         |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code>        | a character string giving the path to the directory with the source ‘.tar.gz’ files to be checked.                                                                                                      |
| <code>check_args</code> | a character vector with arguments to be passed to R CMD <code>check</code> , or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively. |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| check_args_db | a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names.                                                                                                                                                                                                                                                                                                         |
| reverse       | a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (default: getOption("repos")), the types of reverse dependencies (default: c("Depends", "Imports", "LinkingTo")), and indicating whether to also check reverse dependencies of reverse dependencies (and so on), or NULL (default), in which case no reverse dependencies are checked. |
| check_env     | a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.                                                                                                                                                                                                                 |
| xvfb          | a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so.                                                                                                                                                                                                                                                                        |
| Ncpus         | the number of parallel processes to use for parallel installation and checking.                                                                                                                                                                                                                                                                                                                                                |
| clean         | a logical indicating whether to remove the downloaded reverse dependency sources.                                                                                                                                                                                                                                                                                                                                              |
| ...           | currently not used.                                                                                                                                                                                                                                                                                                                                                                                                            |
| all           | a logical indicating whether to also summarize the reverse dependencies checked.                                                                                                                                                                                                                                                                                                                                               |
| full          | a logical indicating whether to also summarize check example timings (if available).                                                                                                                                                                                                                                                                                                                                           |

## Details

`check_packages_in_dir` allows to conveniently check source package ‘.tar.gz’ files in the given directory `dir`, along with their reverse dependencies as controlled by `reverse`.

If needed, the source ‘.tar.gz’ files of the reverse dependencies to be checked as well are downloaded into `dir` (and removed at the end if `clean` is true). Next, all packages (additionally) needed for checking are installed to the ‘Library’ subdirectory of `dir`. Then, all ‘.tar.gz’ files are checked using the given arguments and environment variables, with outputs and messages to files in the ‘Outputs’ subdirectory of `dir`. The ‘\*.Rcheck’ directories with the check results of the reverse dependencies are renamed by prefixing their base names with ‘`rdepends_`’.

Results and timings can conveniently be summarized using `summarize_check_packages_in_dir_results` and `summarize_check_packages_in_dir_timings`, respectively.

Installation and checking is performed in parallel if `Ncpus` is greater than one: this will use `mclapply` on Unix and `parLapply` on Windows.

## Note

This functionality is still experimental: interfaces may change in future versions.

---

codoc*Check Code/Documentation Consistency*

---

## Description

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. codoc compares names and optionally also corresponding positions and default values of the arguments of functions. codocClasses and codocData compare slot names of S4 classes and variable names of data sets, respectively.

## Usage

```
codoc(package, dir, lib.loc = NULL,
 use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```

## Arguments

|            |                                                                                                                                                                                                                             |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package    | a character string naming an installed package.                                                                                                                                                                             |
| dir        | a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if package is not given. |
| lib.loc    | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                          |
| use.values | if FALSE, do not use function default values when comparing code and docs. Otherwise, compare <i>all</i> default values if TRUE, and only the ones documented in the usage otherwise (default).                             |
| verbose    | a logical. If TRUE, additional diagnostics are printed.                                                                                                                                                                     |

## Details

The purpose of codoc is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the **base** package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument `use.values`. Synopsis sections are used if present; their occurrence is reported if `verbose` is true.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames

in documentation objects obtained by suitably editing ‘templates’ created by [prompt](#) are recognized by codocData and used provided that the documentation object is for a single data frame (i.e., only has one alias). codocClasses analogously handles slot names for classes in documentation objects obtained by editing shells created by [promptClass](#).

Help files named ‘*pkgnname*-defunct.Rd’ for the appropriate *pkgnname* are checked more loosely, as they may have undocumented arguments.

### Value

codoc returns an object of class “codoc”. Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements code and docs, giving the corresponding arguments obtained from the function’s code and documented usage).

codocClasses and codocData return objects of class “codocClasses” and “codocData”, respectively, with a structure similar to class “codoc”.

There are print methods for nicely displaying the information contained in such objects.

### Note

The default for use.values has been changed from FALSE to NULL, for R versions 1.9.0 and later.

compactPDF

*Compact PDF Files*

### Description

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build --compact-vignettes.

### Usage

```
compactPDF(paths,
 qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")),
 gs_cmd = Sys.getenv("R_GSCMD", ""),
 gs_quality = Sys.getenv("GS_QUALITY", "none"),
 gs_extras = character())

S3 method for class compactPDF
format(x, ratio = 0.9, diff = 1e4, ...)
```

### Arguments

|       |                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| paths | A character vector of paths to PDF files, or a length-one character vector naming a directory, when all ‘.pdf’ files in that directory will be used. |
| qpdf  | Character string giving the path to the qpdf command. If empty, qpdf will not be used.                                                               |

|             |                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| gs_cmd      | Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to ‘gswin32c.exe’ or ‘gswin64c.exe’. If “” (the default), the function will try to find a platform-specific path to GhostScript where required. |
| gs_quality  | A character string indicating the quality required: the options are “none” (so GhostScript is not used), “printer” (300dpi), “ebook” (150dpi) and “screen” (72dpi).                                                                                                |
| gs_extras   | An optional character vector of further options to be passed to GhostScript.                                                                                                                                                                                       |
| x           | An object of class “compactPDF”.                                                                                                                                                                                                                                   |
| ratio, diff | Limits for reporting: files are only reported whose sizes are reduced both by a factor of ratio and by diff bytes.                                                                                                                                                 |
| ...         | Further arguments to be passed to or from other methods.                                                                                                                                                                                                           |

## Details

This by default makes use of qpdf, available from <http://qpdf.sourceforge.net/> (including as a Windows binary) and included with the CRAN Mac OS X distribution of R. If gs\_cmd is non-empty and gs\_quality != “none”, GhostScript will be used first, then qpdf if it is available. If gs\_quality != “none” and gs\_cmd is “”, an attempt will be made to find a GhostScript executable.

qpdf and/or gs\_cmd are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of qpdf is to (losslessly) compress both PDF streams and objects. GhostScript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality “ebook” is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains: R’s pdf device prior to R 2.14.0 did not use it, and older vignette PDFs often benefit from being re-generated. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX’s pdflatex. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and qpdf are selected (when gs\_quality != “none” and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

## Value

An object of class c(“compactPDF”, “data.frame”). This has two columns, the old and new sizes in bytes for the files that were changed.

There are format and print methods: the latter passes ... to the format method, so will accept ratio and diff arguments.

## Note

The external tools used may change in future releases.

Versions of GhostScript 9.06 and later give several times better compression than 9.05 on some vignettes in CRAN packages.

[resaveRdaFiles](#).

Many other (and sometimes more effective) tools to compact PDF files are available, including Adobe Acrobat (not Reader). See the ‘Writing R Extensions’ manual.

---

delimMatch

*Delimited Pattern Matching*

---

**Description**

Match delimited substrings in a character vector, with proper nesting.

**Usage**

```
delimMatch(x, delim = c("{", "}"), syntax = "Rd")
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                         |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a character vector.                                                                                                                                                                                                                                                                     |
| delim  | a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.                                                                                                                                                      |
| syntax | currently, always the string "Rd" indicating Rd syntax (i.e., '%' starts a comment extending till the end of the line, and '\' escapes). Future versions might know about other syntax, perhaps via ‘syntax tables’ allowing to flexibly specify comment, escape, and quote characters. |

**Value**

An integer vector of the same length as x giving the starting position (in characters) of the first match, or -1 if there is none, with attribute "match.length" giving the length (in characters) of the matched text (or -1 for no match).

**See Also**

[regexp](#) for ‘simple’ pattern matching.

**Examples**

```
x <- c("\\value{foo}", "function(bar)")
delimMatch(x)
delimMatch(x, c("(", ")"))
```

|               |                                  |
|---------------|----------------------------------|
| dependsOnPkgs | <i>Find Reverse Dependencies</i> |
|---------------|----------------------------------|

### Description

Find ‘reverse’ dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

### Usage

```
dependsOnPkgs(pkgs,
 dependencies = c("Depends", "Imports", "LinkingTo"),
 recursive = TRUE, lib.loc = NULL,
 installed =
 installed.packages(lib.loc, fields = "Enhances"))
```

### Arguments

|              |                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs         | a character vector of package names.                                                                                                                                                 |
| dependencies | a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector. |
| recursive    | logical: should reverse dependencies of reverse dependencies (and so on) be included?                                                                                                |
| lib.loc      | a character vector of R library trees, or NULL for all known trees (see <a href="#">.libPaths</a> ).                                                                                 |
| installed    | a result of calling <a href="#">installed.packages</a> .                                                                                                                             |

### Value

A character vector of package names, which does not include any from pkgs.

### Examples

```
there are few dependencies in a vanilla R installation:
lattice may not be installed
dependsOnPkgs("lattice")
```

|                       |                                                  |
|-----------------------|--------------------------------------------------|
| encoded_text_to_latex | <i>Translate non-ASCII Text to LaTeX Escapes</i> |
|-----------------------|--------------------------------------------------|

### Description

Translate non-ASCII characters in text to LaTeX escape sequences.

### Usage

```
encoded_text_to_latex(x,
 encoding = c("latin1", "latin2", "latin9",
 "UTF-8", "utf8"))
```

### Arguments

- `x` a character vector.  
`encoding` the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX's `inputenc` package.

### Details

Non-ASCII characters in `x` are replaced by an appropriate LaTeX escape sequence, or '?' if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to '\-'.

### Value

A character vector of the same length as `x`.

### See Also

[iconv](#)

### Examples

```

x <- "fa\xE7ile"
encoded_text_to_latex(x, "latin1")
Not run:
create a tex file to show the upper half of 8-bit charsets

list_files_with_type(dir, type, all.files = FALSE,
 full.names = TRUE, OS_subdirs = .OStype())

```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                              |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | character vector giving file paths.                                                                                                                                                                                                                                                          |
| <code>compression</code> | logical: should compression extension ‘.gz’, ‘.bz2’ or ‘.xz’ be removed first?                                                                                                                                                                                                               |
| <code>dir</code>         | a character string with the path name to a directory.                                                                                                                                                                                                                                        |
| <code>exts</code>        | a character vector of possible file extensions (excluding the leading dot).                                                                                                                                                                                                                  |
| <code>all.files</code>   | a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used.                                                                                                                                                                                               |
| <code>full.names</code>  | a logical indicating whether the full paths of the files found are returned (default), or just the file names.                                                                                                                                                                               |
| <code>type</code>        | a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are “code” (R code), “data” (data sets), “demo” (demos), “docs” (R documentation), and “vignette” (vignettes).                                              |
| <code>OS_subdirs</code>  | a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable <code>R_OSTYPE</code> , or if this is empty, the value of <code>.Platform\$OS.type</code> , is used. |

## Details

`file_ext` returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)

`file_path_as_absolute` turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for `normalizePath`. Currently, `x` must be a single existing path.

`file_path_sans_ext` returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)

`list_files_with_exts` returns the paths or names of the files in directory `dir` with extension matching one of the elements of `exts`. Note that by default, full paths are returned, and that only visible files are used.

`list_files_with_type` returns the paths of the files in `dir` of the given ‘type’, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of `OS_subdirs`. Note that by default, full paths are returned, and that only visible files are used.

## See Also

`file.path`, `file.info`, `list.files`

## Examples

```
dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))
```

---

getDepList

*Functions to Retrieve Dependency Information*

---

## Description

Given a dependency matrix, will create a `DependsList` object for that package which will include the dependencies for that matrix, which ones are installed, which unresolved dependencies were found online, which unresolved dependencies were not found online, and any R dependencies.

## Usage

```
getDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE,
 reduce = TRUE, lib.loc = NULL)

pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE,
 lib.loc = NULL)
```

## Arguments

|                       |                                                                                                         |
|-----------------------|---------------------------------------------------------------------------------------------------------|
| <code>depMtrx</code>  | A dependency matrix as from <code>package.dependencies</code>                                           |
| <code>pkg</code>      | The name of the package                                                                                 |
| <code>instPkgs</code> | A matrix specifying all packages installed on the local system, as from <code>installed.packages</code> |

|                        |                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>recursive</code> | Whether or not to include indirect dependencies                                                                                                         |
| <code>local</code>     | Whether or not to search only locally                                                                                                                   |
| <code>reduce</code>    | Whether or not to collapse all sets of dependencies to a minimal value                                                                                  |
| <code>lib.loc</code>   | What libraries to use when looking for installed packages. <code>NULL</code> indicates all library directories in the user's <code>.libPaths()</code> . |

## Details

The function `pkgDepends` is a convenience function which wraps `getDepList` and takes as input a package name. It will then query `installed.packages` and also generate a dependency matrix, calling `getDepList` with this information and returning the result.

These functions will retrieve information about the dependencies of the matrix, resulting in a `DependsList` object. This is a list with four elements:

**Depends** A vector of the dependencies for this package.

**Installed** A vector of the dependencies which have been satisfied by the currently installed packages.

**Found** A list representing the dependencies which are not in `Installed` but were found online. This list has element names which are the URLs for the repositories in which packages were found and the elements themselves are vectors of package names which were found in the respective repositories. If `local = TRUE`, the `Found` element will always be empty.

**R** Any R version dependencies.

If `recursive` is `TRUE`, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If `recursive` is `FALSE`, only the dependencies directly stated by the package will be used.

If `local` is `TRUE`, the system will only look at the user's local install and not online to find unresolved dependencies.

If `reduce` is `TRUE`, the system will collapse the fields in the `DependsList` object such that a minimal set of dependencies are specified (for instance if there was '`foo, foo (>= 1.0.0), foo (>= 1.3.0)`', it would only return '`foo (>= 1.3.0)`').

## Value

An object of class "DependsList".

## Author(s)

Jeff Gentry

## See Also

[installFoundDepends](#)

## Examples

```
pkgDepends("tools", local = FALSE)
```

---

getVignetteInfo      *Get information on installed vignettes.*

---

## Description

This function gets information on installed vignettes.

## Usage

```
getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)
```

## Arguments

|         |                                                                      |
|---------|----------------------------------------------------------------------|
| package | Which package to look in, or NULL for all packages.                  |
| lib.loc | Which library to look in.                                            |
| all     | Whether to search all installed packages, or just attached packages. |

## Value

A matrix with columns

|         |                                                 |
|---------|-------------------------------------------------|
| Package | the name of the package                         |
| Dir     | the directory where the package is installed    |
| Topic   | the name of the vignette                        |
| File    | the base filename of the source of the vignette |
| Title   | the title of the vignette                       |
| R       | the tangled R source from the vignette          |
| PDF     | the PDF or HTML file for display                |

## Note

The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

## See Also

[pkgVignettes](#) is a similar function that can work on an uninstalled package.

## Examples

```
getVignetteInfo("grid")
```

---

HTMLheader*Generate a standard HTML header for R help*

---

**Description**

This function generates the standard HTML header used on R help pages.

**Usage**

```
HTMLheader(title = "R", logo = TRUE, up = NULL,
 top = file.path(Rhome, "doc/html/index.html"),
 Rhome = "",
 css = file.path(Rhome, "doc/html/R.css"),
 headerTitle = paste("R:", title),
 outputEncoding = "UTF-8")
```

**Arguments**

|                       |                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------|
| <b>title</b>          | The title to display and use in the HTML headers. Should have had any HTML escaping already done. |
| <b>logo</b>           | Whether to display the R logo after the title.                                                    |
| <b>up</b>             | Which page (if any) to link to on the “up” button.                                                |
| <b>top</b>            | Which page (if any) to link to on the “top” button.                                               |
| <b>Rhome</b>          | A <b>relative</b> path to the R home directory. See the ‘Details’.                                |
| <b>css</b>            | The relative URL for the Cascading Style Sheet.                                                   |
| <b>headerTitle</b>    | The title used in the headers.                                                                    |
| <b>outputEncoding</b> | The declared encoding for the whole page.                                                         |

**Details**

The up and top links should be relative to the current page. The Rhome path default works with dynamic help; for static help, a relative path (e.g. ‘.../..’) to it should be used.

**Value**

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

**Examples**

```
cat(HTMLheader("This is a sample header"), sep="\n")
```

---

**HTMLlinks***Collect HTML Links from Package Documentation*

---

**Description**

Compute relative file paths for URLs to other package's installed HTML documentation.

**Usage**

```
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
```

**Arguments**

- |                      |                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>pkgDir</code>  | the top-level directory of an installed package. The default indicates no package.                                       |
| <code>lib.loc</code> | character vector describing the location of R library trees to scan: the default indicates <a href="#">.libPaths()</a> . |
| <code>level</code>   | Which level(s) to include.                                                                                               |

**Details**

`findHTMLlinks` tries to resolve links from one help page to another. It uses in decreasing priority

- The package in `pkgDir`: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by `lib.loc` in the order of the trees and alphabetically within a library tree (level 2).

**Value**

A named character vector of file paths, relative to the 'html' directory of an installed package. So these are of the form "`"../../somepkg/html/sometopic.html"`".

**Author(s)**

Duncan Murdoch, Brian Ripley

---

**installFoundDepends**    *A function to install unresolved dependencies*

---

**Description**

This function will take the `Found` element of a `pkgDependsList` object and attempt to install all of the listed packages from the specified repositories.

**Usage**

```
installFoundDepends(depPkgList, ...)
```

**Arguments**

- |            |                                                          |
|------------|----------------------------------------------------------|
| depPkgList | A Found element from a pkgDependsList object             |
| ...        | Arguments to pass on to <a href="#">install.packages</a> |

**Details**

This function takes as input the Found list from a pkgDependsList object. This list will have element names being URLs corresponding to repositories and the elements will be vectors of package names. For each element, [install.packages](#) is called for that URL to install all packages listed in the vector.

**Author(s)**

Jeff Gentry

**See Also**

[pkgDepends](#), [install.packages](#)

**Examples**

```
Set up a temporary directory to install packages to
tmp <- tempfile()
dir.create(tmp)

pDL <- pkgDepends("tools", local = FALSE)
installFoundDepends(pDL$Found, destdir = tmp)
```

*make\_translations\_pkg Package the Current Translations in the R sources*

**Description**

A utility for R Core members to prepare a package of updated translations.

**Usage**

```
make_translations_pkg(srcdir, outDir = ".", append = "-1")
```

**Arguments**

- |        |                                                                                         |
|--------|-----------------------------------------------------------------------------------------|
| srcdir | The R source directory.                                                                 |
| outDir | The directory into which to place the prepared package.                                 |
| append | The suffix for the package version number, e.g. 3.0.0-1 will be the default in R 3.0.0. |

**Details**

This extracts the translations in a current R source distribution and packages them as a source package called **translations** which can be distributed on CRAN and installed by [update.packages](#). This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges.

The package has a ‘Depends’ field which restricts it to versions 3.x.\* for a single x.

---

`md5sum`*Compute MD5 Checksums*

---

### Description

Compute the 32-byte MD5 checksums of one or more files.

### Usage

```
md5sum(files)
```

### Arguments

`files` character. The paths of file(s) to be check-summed.

### Value

A character vector of the same length as `files`, with names equal to `files`. The elements will be NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

On Windows all files are read in binary mode (as the `md5sum` utilities there do): on other OSes the files are read in the default way.

### See Also

[checkMD5sums](#)

### Examples

```
as.vector(md5sum(dir(R.home(), pattern = "^\$COPY", full.names = TRUE)))
```

---

`package.dependencies`*Check Package Dependencies*

---

### Description

Parses and checks the dependencies of a package against the currently installed version of R (and other packages).

### Usage

```
package.dependencies(x, check = FALSE,
 depLevel =
 c("Depends", "Imports", "Suggests"))
```

### Arguments

`x` A matrix of package descriptions as returned by [available.packages](#).  
`check` If TRUE, return logical vector of check results. If FALSE, return parsed list of dependencies.  
`depLevel` Whether to look for Depends or Suggests level dependencies.

## Details

Currently we only check if the package conforms with the currently running version of R. In the future we might add checks for inter-package dependencies.

## See Also

[update.packages](#)

**package\_dependencies** *Computations on the Dependency Hierarchy of Packages*

## Description

Find (recursively) dependencies or reverse dependencies of packages.

## Usage

```
package_dependencies(packages = NULL, db,
 which = c("Depends", "Imports", "LinkingTo"),
 recursive = FALSE, reverse = FALSE)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>packages</code>  | a character vector of package names.                                                                                                                                                                                                                                               |
| <code>db</code>        | character matrix as from <code>available.packages()</code> , or data frame variants thereof. Alternatively, a package database like the one available from <a href="http://cran.R-project.org/web/packages/packages.rds">http://cran.R-project.org/web/packages/packages.rds</a> . |
| <code>which</code>     | a character vector listing the types of dependencies, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances".                 |
| <code>recursive</code> | logical: should (reverse) dependencies of (reverse) dependencies (and so on) be included?                                                                                                                                                                                          |
| <code>reverse</code>   | logical: if FALSE (default), regular dependencies are calculated, otherwise reverse dependencies.                                                                                                                                                                                  |

## Value

Named list with one element for each package in argument `packages`, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the `db`, `NULL` entries are returned, as opposed to `character(0)` entries which indicate no dependencies.

## See Also

[dependsOnPkgs](#), and [package.dependencies](#) for checking dependencies

## Examples

```
Not run:
pdb <- available.packages()
deps <- package_dependencies(packages = "MASS", pdb,
 which = c("Depends", "Imports", "LinkingTo", "Suggests"),
 recursive = TRUE, reverse = TRUE)
length(deps$MASS)

End(Not run)
```

parseLatex

*These experimental functions work with a subset of LaTeX code.*

## Description

The `parseLatex` function parses LaTeX source, producing a structured object; `deparseLatex` reverses the process. The `latexToUtf8` function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

## Usage

```
parseLatex(text, filename = deparse(substitute(text)),
 verbose = FALSE,
 verbatim = c("verbatim", "verbatim*",
 "Sinput", "Soutput"))
deparseLatex(x, dropBraces = FALSE)
latexToUtf8(x)
```

## Arguments

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>text</code>       | A character vector containing LaTeX source code.                                     |
| <code>filename</code>   | A filename to use in syntax error messages.                                          |
| <code>verbose</code>    | If TRUE, print debug error messages.                                                 |
| <code>verbatim</code>   | A character vector containing the names of LaTeX environments holding verbatim text. |
| <code>x</code>          | A "LaTeX" object.                                                                    |
| <code>dropBraces</code> | Drop unnecessary braces when displaying a "LaTeX" object.                            |

## Details

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in two forms: the `\verb` macro (with single character delimiters), and environments whose names are listed in the `verbatim` argument.

**Value**

The `parseLatex()` function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex\_tag" attribute identifying its syntactic role.

The `deparseLatex()` function returns a single element character vector, possibly containing embedded newlines.

The `latexToUtf8()` function returns a modified version of the "LaTeX" object that was passed to it.

**Author(s)**

Duncan Murdoch

**Examples**

```
latex <- parseLatex("fa\\c{c}ile")
deparseLatex(latexToUtf8(latex))
```

**parse\_Rd**

*Parse an Rd file*

**Description**

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

**Usage**

```
parse_Rd(file, srcfile = NULL, encoding = "unknown",
 verbose = FALSE, fragment = FALSE, warningCalls = TRUE)
S3 method for class Rd
print(x, deparse = FALSE, ...)
S3 method for class Rd
as.character(x, deparse = FALSE, ...)
```

**Arguments**

|                           |                                                                                                                     |
|---------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>file</code>         | A filename or text-mode connection. At present filenames work best.                                                 |
| <code>srcfile</code>      | NULL, or a "srcfile" object. See the 'Details' section.                                                             |
| <code>encoding</code>     | Encoding to be assumed for input strings.                                                                           |
| <code>verbose</code>      | Logical indicating whether detailed parsing information should be printed.                                          |
| <code>fragment</code>     | Logical indicating whether file represents a complete Rd file, or a fragment.                                       |
| <code>warningCalls</code> | Logical: should parser warnings include the call?                                                                   |
| <code>x</code>            | An object of class Rd.                                                                                              |
| <code>deparse</code>      | If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object. |
| <code>...</code>          | Further arguments to be passed to or from other methods.                                                            |

**Details**

This function parses ‘Rd’ files according to the specification given in <http://developer.r-project.org/parseRd.pdf>.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

**Value**

`parse_Rd` returns an object of class “Rd”. The internal format of this object is subject to change. The `as.character()` and `print()` methods defined for the class return character vectors and print them, respectively.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the `encoding` argument. All text in files is translated to the UTF-8 encoding in the parsed object.

---

pskill

*Kill a Process*

---

**Description**

`pskill` sends a signal to a process, usually to terminate it.

**Usage**

```
pskill(pid, signal = SIGTERM)

SIGHUP
SIGINT
SIGQUIT
SIGKILL
SIGTERM
SIGSTOP
SIGTSTP
SIGCHLD
SIGUSR1
SIGUSR2
```

### Arguments

|                     |                                                                                        |
|---------------------|----------------------------------------------------------------------------------------|
| <code>pid</code>    | positive integers: one or more process IDs as returned by <a href="#">Sys.getpid</a> . |
| <code>signal</code> | integer, most often one of the symbolic constants.                                     |

### Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only SIGINT and SIGTERM). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a `kill` system call to send a signal to a process, most often to terminate it. Function `pskill` provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, `Ctrl-C` sends `SIGINT`, `Ctrl-\` sends `SIGQUIT` and `Ctrl-Z` sends `SIGTSTP`: that and `SIGSTOP` suspend a process which can be resumed by `SIGCONT`.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The `SIG*` objects contain the appropriate integer values for the current platform (or `NA_INTEGER_` if the signal is not defined).

Only `SIGINT` and `SIGKILL` will be defined on Windows, and `pskill` will always use the Windows system call `TerminateProcess`.

### Value

A logical vector of the same length as `pid`, `TRUE` (for success) or `FALSE`, invisibly.

### See Also

Package **parallel** has several means to launch child processes which record the process IDs.  
[psnice](#)

### Examples

```
Not run:
pskill(c(237, 245), SIGKILL)

End(Not run)
```

### Description

Get or set the ‘niceness’ of the current process, or one or more other processes.

### Usage

```
psnice(pid = Sys.getpid(), value = NA_integer_)
```

### Arguments

|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <code>pid</code>   | positive integers: the process IDs of one or more processes: defaults to the R session process. |
| <code>value</code> | The niceness to be set, or <code>NA</code> for an enquiry.                                      |

## Details

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as top report the priority and not the niceness. Niceness is used by the utility ‘/usr/bin/renice’: ‘/usr/bin/nice’ (and /usr/bin/renice -n) specifies an *increment* in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

## Value

An integer vector of *previous* niceness values, NA if unknown for any reason.

## See Also

Various functions in package **parallel** create child processes whose priority may need to be changed.  
[pskill](#).

## Description

Functions for performing various quality checks.

## Usage

```
checkDocFiles(package, dir, lib.loc = NULL)
checkDocStyle(package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods(package, dir, lib.loc = NULL)
```

## Arguments

|         |                                                                                                                                                                                                                                |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package.                                                                                                                                                                                |
| dir     | a character string specifying the path to a package’s root source directory. This should contain the subdirectories ‘R’ (for R code) and ‘man’ with R documentation sources (in Rd format). Only used if package is not given. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                             |

## Details

`checkDocFiles` checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and ‘over-documented’ arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

`checkDocStyle` investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd \method markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With \method now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by `checkDocStyle`.)

`checkReplaceFuns` checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named `value`.

`checkS3methods` checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method *may* be called `formula` even if this is not the name used by the generic. The rules when ... is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to `UseMethod` in their body, internal S3 generics (see [InternalMethods](#)), and S3 group generics (see [Math](#)). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the **base** package and (currently) the packages **graphics**, **stats**, and **utils** added in R 1.9.0 by splitting the former **base**, and, if an installed package is tested, also in the loaded namespaces/packages listed in the package’s ‘DESCRIPTION’ Depends field.

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the **base** package), after possibly detaching an already loaded version of the package.

## Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are print methods for nicely displaying the information contained in such objects.

## Description

These functions take the output of the `parse_Rd` function and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

## Usage

```
Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,
 Links = NULL, Links2 = NULL,
 stages = "render", outputEncoding = "UTF-8",
 dynamic = FALSE, no_links = FALSE, fragment = FALSE,
```

```

stylesheet = "R.css", ...)

Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
 stages = "render", outputEncoding = "",
 fragment = FALSE, options, ...)

Rd2latex(Rd, out = "", defines = .Platform$OS.type,
 stages = "render", outputEncoding = "ASCII",
 fragment = FALSE, ..., writeEncoding = TRUE)

Rd2ex(Rd, out = "", defines = .Platform$OS.type,
 stages = "render", outputEncoding = "UTF-8",
 commentDontrun = TRUE, ...)

```

## Arguments

|                |                                                                                                         |
|----------------|---------------------------------------------------------------------------------------------------------|
| Rd             | a filename or Rd object to use as input.                                                                |
| out            | a filename or connection object to which to write the output.                                           |
| package        | the package to list in the output.                                                                      |
| defines        | string(s) to use in #ifdef tests.                                                                       |
| stages         | at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below. |
| outputEncoding | see the 'Encodings' section below.                                                                      |
| dynamic        | logical: set links for render-time resolution by dynamic help system.                                   |
| no_links       | logical: suppress hyperlinks to other help topics. Used by R CMD <a href="#">Rdconv</a> .               |
| fragment       | logical: should fragments of Rd files be accepted? See the notes below.                                 |
| stylesheet     | character: a URL for a stylesheet to be used in the header of the HTML output page.                     |
| Links, Links2  | NULL or a named (by topics) character vector of links, as returned by <a href="#">findHTMLlinks</a> .   |
| options        | An optional named list of options to pass to <a href="#">Rd2txt_options</a> .                           |
| ...            | additional parameters to pass to <a href="#">parse_Rd</a> when Rd is a filename.                        |
| writeEncoding  | should \inputencoding lines be written in the file for non-ASCII encodings?                             |
| commentDontrun | should \dontrun sections be commented out?                                                              |

## Details

These functions convert help documents: Rd2HTML produces HTML, Rd2txt produces plain text, Rd2latex produces LaTeX. Rd2ex extracts the examples in the format used by [example](#) and R utilities.

Each of the functions accepts a filename for an Rd file, and will use [parse\\_Rd](#) to parse it before applying the conversions or checks.

The difference between arguments Link and Link2 is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Note that the default for Rd2latex is to output ASCII, including using the second option of \enc markup. This was chosen because use of UTF-8 in LaTeX requires version '2005/12/01' or later, and even with that version the coverage of UTF-8 glyphs is not extensive (and not even as complete as Latin-1).

Rd2txt will format text paragraphs to a width determined by `width`, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

Rd2txt will use directional quotes (see [sQuote](#)) if option "useFancyQuotes" is true (the default) and the current encoding is UTF-8.

Various aspects of formatting by Rd2txt are controlled by the `options` argument, documented with the [Rd2txt\\_options](#) function. Changes made using `options` are temporary, those made with [Rd2txt\\_options](#) are persistent.

When `fragment = TRUE`, the Rd file will be rendered with no processing of \Sexpr elements or conditional defines using #ifdef or #ifndef. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

### Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For Rd2latex, the output name is given an attribute "latexEncoding" giving the encoding of the file in a form suitable for use with the LaTeX 'inputenc' package.

### Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the 'encoding' section for there to be any hope of correct rendering.

For output, the `outputEncoding` argument will be used: `outputEncoding = ""` will choose the native encoding for the current system.

If the text cannot be converted to the `outputEncoding`, byte substitution will be used (see [iconv](#)): Rd2latex and Rd2ex give a warning.

### Note

The \Sexpr macro is a new addition to Rd files. It includes R code that will be executed at one of three times: *build* time (when a package's source code is built into a tarball), *install* time (when the package is installed or built into a binary package), and *render* time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2013-09-25 at 07:53:37,
2. installed on 2013-09-25 at 07:53:37, and
3. rendered on 2013-09-25 at 07:59:24.

## Examples

```
Not run:
Simulate install and rendering of this page in HTML and text format:

Rd <- file.path("src/library/tools/man/Rd2HTML.Rd")

outfile <- tempfile(fileext = ".html")
browseURL(Rd2HTML(Rd, outfile, package = "tools",
 stages = c("install", "render")))

outfile <- tempfile(fileext = ".txt")
file.show(Rd2txt(Rd, outfile, package = "tools",
 stages = c("install", "render")))

checkRd(Rd) # A stricter test than Rd2HTML uses

End(Not run)
```

Rd2txt\_options

*Set formatting options for text help*

## Description

This function sets various options for displaying text help.

## Usage

```
Rd2txt_options(...)
```

## Arguments

... A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

## Details

This function persistently sets various formatting options for the [Rd2txt](#) function which is used in displaying text format help. Currently defined options are:

- width** (default 80): The width of the output page.
- minIndent** (default 10): The minimum indent to use in a list.
- extraIndent** (default 4): The extra indent to use in each level of nested lists.
- sectionIndent** (default 5): The indent level for a section.
- sectionExtra** (default 2): The extra indentation for each nested section level.
- itemBullet** (default "\* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.
- enumFormat** : A function to format item numbers in enumerated lists.
- showURLs** (default FALSE): Whether to show URLs when expanding \href tags.
- code\_quote** (default TRUE): Whether to render \code and similar with single quotes.
- underline\_titles** default TRUE): Whether to render section titles with underlines (via backspacing).

**Value**

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

**Author(s)**

Duncan Murdoch

**See Also**

[Rd2txt](#)

**Examples**

```
The itemBullet is locale-specific
saveOpts <- Rd2txt_options()
saveOpts
Rd2txt_options(minIndent = 4)
Rd2txt_options()
Rd2txt_options(saveOpts)
Rd2txt_options()
```

**Rdiff**

*Difference R Output Files*

**Description**

Given two R output files, compute differences ignoring headers, footers and some other differences.

**Usage**

```
Rdiff(from, to, useDiff = FALSE, forEx = FALSE,
 nullPointers = TRUE, Log = FALSE)
```

**Arguments**

|                           |                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------|
| <code>from, to</code>     | filepaths to be compared                                                                    |
| <code>useDiff</code>      | should diff always be used to compare results?                                              |
| <code>forEx</code>        | logical: extra pruning for ‘-Ex.Rout’ files to exclude the header.                          |
| <code>nullPointers</code> | logical: should the displayed addresses of pointers be set to 0x00000000 before comparison? |
| <code>Log</code>          | logical: should the returned value include a log of differences found?                      |

## Details

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see [sQuote](#)) and on Windows, Windows' so-called ‘smart quotes’, are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g. `<environment: 0x12345678>`) are mapped to `0x00000000`. The files are then compared line-by-line. If there are the same number of lines and `useDiff` is false, a simple diff-like display of differences is printed (which ignores differences in consecutive spaces), otherwise `diff -bw` is called on the edited files. (This tries to ignore all differences in whitespace: note that flag ‘`-w`’ is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions.)

This can compare uncompressed PDF files, ignoring differences in creation and modification dates.

## Value

If `Log` is true, a list with components `status` (see below) and `out`, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator, `0L` if and only if no differences were found.

## See Also

The shell script run as R CMD Rdif.

---

Rdindex

*Generate Index from Rd Files*

---

## Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

## Usage

```
Rdindex(RdFiles, outFile = "", type = NULL,
 width = 0.9 * getOption("width"), indent = NULL)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>RdFiles</code> | a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package.                                                                                                                                                      |
| <code>outFile</code> | a connection, or a character string naming the output file to print to. “ <code>”</code> (the default) indicates output to the console.                                                                                                                                                                                                      |
| <code>type</code>    | a character string giving the documentation type of the Rd files to be included in the index, or <code>NULL</code> (the default). The type of an Rd file is typically specified via the <code>\docType</code> tag; if <code>type</code> is “ <code>data</code> ”, Rd files whose <code>only</code> keyword is datasets are included as well. |
| <code>width</code>   | a positive integer giving the target column for wrapping lines in the output.                                                                                                                                                                                                                                                                |
| <code>indent</code>  | a positive integer specifying the indentation of the second column. Must not be greater than <code>width/2</code> , and defaults to <code>width/3</code> .                                                                                                                                                                                   |

## Details

If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

**RdTextFilter**

*Select text in an Rd file.*

## Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

## Usage

```
RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
 drop = character(), keep = character())
```

## Arguments

|             |                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------|
| ifile       | An input file specified as a filename or connection, or an "Rd" object from <a href="#">parse_Rd</a> . |
| encoding    | An encoding name to pass to <a href="#">parse_Rd</a> .                                                 |
| keepSpacing | Whether to try to leave the text in the same lines and columns as in the original file.                |
| drop        | Additional sections of the Rd to drop.                                                                 |
| keep        | Sections of the Rd file to keep.                                                                       |

## Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as [aspell](#) can check only the text and report the position in the original file. (If keepSpacing is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags \S3method, \S4method, \command, \docType, \email, \encoding, \file, \keyword, \link, \linkS4class, \method, \pkg, and \var are skipped. Additional tags can be skipped by listing them in the drop argument; listing tags in the keep argument will stop them from being skipped. It is also possible to keep any of the c("RCODE", "COMMENT", "VERB") tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

## Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

## Note

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

## Author(s)

Duncan Murdoch

## See Also

[aspell](#), for which this is an acceptable filter.

---

Rdutils

*Rd Utilities*

---

## Description

Utilities for computing on the information in Rd objects.

## Usage

```
Rd_db(package, dir, lib.loc = NULL)
```

## Arguments

|         |                                                                                                                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package.                                                                                                                                                         |
| dir     | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'man' with R documentation sources (in Rd format). Only used if package is not given. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.      |

## Details

`Rd_db` builds a simple database of all Rd objects in a package, as a list of the results of running [parse\\_Rd](#) on the Rd source files in the package and processing platform conditionals.

## See Also

[parse\\_Rd](#)

## Examples

```
Build the Rd db for the (installed) base package.
db <- Rd_db("base")

Keyword metadata per Rd object.
keywords <- lapply(db, tools:::Rd_get_metadata, "keyword")
Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
The 5 most frequent ones:
rev(kw_table)[1 : 5]
The "most informative" ones:
kw_table[kw_table == 1]

Concept metadata per Rd file.
concepts <- lapply(db, tools:::Rd_get_metadata, "concept")
How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
How many concept entries altogether?
length(unlist(concepts))
```

read.00Index

*Read 00Index-style Files***Description**

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

**Usage**

```
read.00Index(file)
```

**Arguments**

**file** the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, **file** can be a [connection](#), which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A character matrix with 2 columns named “Item” and “Description” which hold the items and descriptions.

**See Also**

[formatDL](#) for the inverse operation of creating a 00Index-style file from items and their descriptions.

readNEWS

*Read R’s NEWS file or a similar one***Description**

Read/check R’s ‘NEWS’ file or a similarly formatted one. This was an experimental feature added in R 2.4.0: as from R 2.12.0 the preferred format is ‘NEWS.Rd’.

**Usage**

```
readNEWS(file = file.path(R.home(), "NEWS"), trace = FALSE,
 chop = c("first", "1", "par1", "keepAll"))
checkNEWS(file = file.path(R.home(), "NEWS"))
```

**Arguments**

**file** the name of the file which the data are to be read from. Alternatively, **file** can be a [connection](#), which will be opened if necessary, and can also be a complete URL. For more details, see the **file** argument of [read.table](#).

**trace** logical indicating if the recursive reading should be traced, i.e., print what it is doing.

**chop** a character string specifying how the news entries should be *chopped*; **chop** = “keepAll” saves the full entries.

## Details

`readNEWS()` reads a pre-R-2.12.0-style ‘NEWS’ file; `checkNEWS()` checks for common errors in formatting. Currently it detects an incorrect number of spaces before the “o” item marker.

If non-ASCII characters are needed, the ‘NEWS’ file may be encoded in UTF-8 with a byte-order mark (BOM) at the beginning, which `readNEWS()` will recognize. Other encodings will display incorrectly on some systems. However, BOMs are discouraged on many systems and not all editors recognize them, so ‘NEWS’ files should normally be written in ASCII.

## Value

`readNEWS()` returns an (S3) object of class “newsTree”; effectively a [list](#) of lists which is a tree of NEWS entries.

`checkNEWS()` returns TRUE if no suspected errors are found, or prints a message for each suspected error and returns FALSE.

Note that this was only ever experimental and will be removed soon, since the NEWS-file format is not longer supported (but there are examples ‘NEWS.0’, ‘NEWS.1’ and perhaps in packages).

---

showNonASCII

*Pick Out Non-ASCII Characters*

---

## Description

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like ‘<fc>’.

## Usage

```
showNonASCII(x)
showNonASCIIfile(file)
```

## Arguments

|      |                     |
|------|---------------------|
| x    | a character vector. |
| file | path to a file.     |

## Details

This was originally written to help detect non-portable text in files in packages.

It prints all element of x which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted via `iconv`(sub = “byte”).

## Value

The elements of x containing non-ASCII characters will be returned invisibly.

## Examples

```
out <- c(
 "fa\xE7ile test of showNonASCII():",
 "\\\details{",
 " This is a good line",
 " This has an \xfcumlaut in it.",
 " OK again.",
 "}")
f <- tempfile()
cat(out, file = f, sep = "\n")

showNonASCIIfile(f)
unlink(f)
```

**startDynamicHelp**

*Start the Dynamic HTML Help System*

## Description

This function starts the internal help server, so that HTML help pages are rendered when requested.

## Usage

```
startDynamicHelp(start = TRUE)
```

## Arguments

|       |                                                                 |
|-------|-----------------------------------------------------------------|
| start | logical: whether to start or shut down the dynamic help system. |
|-------|-----------------------------------------------------------------|

## Details

This function starts the internal HTTP server, which runs on the loopback interface (127.0.0.1). If `options("help.ports")` is set to a vector of integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.

If the server cannot be started or is disabled, `help.start` will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for 127.0.0.1.

## Value

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

**See Also**

[help.start](#) and [help\(help\\_type = "html"\)](#) will attempt to start the HTTP server if required  
[Rd2HTML](#) is used to render the package help pages.

---

SweaveTeXFilter

*Strip R code out of Sweave file*

---

**Description**

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

**Usage**

```
SweaveTeXFilter(ifile, encoding = "unknown")
```

**Arguments**

|          |                                                      |
|----------|------------------------------------------------------|
| ifile    | Input file or connection.                            |
| encoding | Text encoding to pass to <a href="#">readLines</a> . |

**Details**

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

**Author(s)**

Duncan Murdoch

**See Also**

[aspell](#), for which this is used with `filter = "Sweave"`.

**testInstalledPackage** *Test Installed Packages***Description**

These functions allow an installed package to be tested, or all base and recommended packages.

**Usage**

```
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
 types = c("examples", "tests", "vignettes"),
 srcdir = NULL, Ropts = "")

testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
 scope = c("both", "base", "recommended"),
 types = c("examples", "tests", "vignettes"),
 srcdir = NULL, Ropts = "")

testInstalledBasic(scope = c("basic", "devel", "both"))
```

**Arguments**

|                             |                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------|
| <code>pkg</code>            | name of an installed package.                                                                        |
| <code>lib.loc</code>        | library path(s) in which to look for the package. See <a href="#">library</a> .                      |
| <code>outDir</code>         | the directory into which to write the output files: this should already exist.                       |
| <code>types</code>          | type(s) of tests to be done.                                                                         |
| <code>errorsAreFatal</code> | logical: should testing terminate at the first error?                                                |
| <code>srcdir</code>         | Optional directory to look for .save files.                                                          |
| <code>Ropts</code>          | Additional options such as ‘-d valgrind’ to be passed to R CMD BATCH when running examples or tests. |
| <code>scope</code>          | Which set(s) should be tested?                                                                       |

**Details**

These tests depend on having the package example files installed (which is the default). If package-specific tests are found in a ‘tests’ directory they can be tested: these are not installed by default, but will be if R CMD INSTALL --install-tests was used. Finally, the R code in any vignettes can be extracted and tested.

Package tests are run in a ‘`pkg-tests`’ subdirectory of ‘`outDir`’, and leave their output there.

`testInstalledBasic` runs the basic tests, if installed. This should be run with LC\_COLLATE=C set: the function tries to set this by it may not work on all OSes. For non-English locales it may be desirable to set environment variables LANGUAGE to ‘en’ and LC\_TIME to ‘C’ to reduce the number of differences from reference results.

The package-specific tests for the base and recommended packages are not normally installed, but `make install-tests` is provided to do so (as well as the basic tests).

**Value**

Invisibly 0L for success, 1L for failure.

---

|                       |                            |
|-----------------------|----------------------------|
| <code>texi2dvi</code> | <i>Compile LaTeX Files</i> |
|-----------------------|----------------------------|

---

### Description

Run `latex` and `bibtex` until all cross-references are resolved and create either a dvi or a PDF file.

### Usage

```
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
 texi2dvi = getOption("texi2dvi"),
 texinputs = NULL, index = TRUE)

texi2pdf(file, clean = FALSE, quiet = TRUE,
 texi2dvi = getOption("texi2dvi"),
 texinputs = NULL, index = TRUE)
```

### Arguments

|                        |                                                                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>      | character. Name of LaTeX source file.                                                                                                                                                                                            |
| <code>pdf</code>       | logical. If TRUE, a PDF file is produced instead of the default dvi file ( <code>texi2dvi</code> command line option ‘ <code>--pdf</code> ’).                                                                                    |
| <code>clean</code>     | logical. If TRUE, all auxiliary files created during the conversion are removed.                                                                                                                                                 |
| <code>quiet</code>     | logical. No output unless an error occurs. Ignored if emulation (see the <code>texi2dvi</code> argument) is used.                                                                                                                |
| <code>texi2dvi</code>  | character (or NULL). Script or program used to compile a TeX file to dvi or PDF, respectively. The default (selected by “” or NULL) is to look for an executable on the path and otherwise emulate the script with system calls. |
| <code>texinputs</code> | NULL or a character vector of paths to add to the LaTeX and bibtex input search paths.                                                                                                                                           |
| <code>index</code>     | logical: should indices be prepared?                                                                                                                                                                                             |

### Details

`texi2pdf` is a wrapper for the common case of `texi2dvi(pdf = TRUE)`.

Despite the name, this is used in R to compile LaTeX files, specifically those generated from vignettes. It ensures that the ‘`R_HOME/share/texmf`’ directory is in the `TEXINPUTS` path, so R style files such as ‘`Sweave`’ and ‘`Rd`’ will be found. The TeX search path used is first the existing `TEXINPUTS` setting (or the current directory if unset), then elements of `texinputs`, then ‘`R_HOME/share/texmf`’ and finally the default path. Analogous changes are made to `BIBINPUTS` and `BSTINPUTS` settings.

MiKTeX has a `texi2dvi` executable but no other Windows TeX installation that we know of does, so emulation is used on e.g. TeXLive installations on Windows.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the ‘`hyperref`’ LaTeX package) even on valid input. The argument `index = FALSE` is provided to allow package manuals to be made when this happens: it uses emulation.

**Value**

Invisible NULL. Used for the side effect of creating a dvi or PDF file in the current working directory (and maybe other files, especially if `clean = FALSE`).

**Note**

There are various versions of the `texi2dvi` script on Unix-alikes and quite a number of bugs have been seen, some of which this R wrapper works around.

One that was present with `texi2dvi` version 4.8 (as supplied on OS X) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike `texi2dvi` script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

**Author(s)**

Originally Achim Zeileis but largely rewritten by R-core.

`toHTML`

*Display an object in HTML.*

**Description**

This generic function generates a complete HTML page from an object.

**Usage**

```
toHTML(x, ...)
S3 method for class packageIQR
toHTML(x, ...)
S3 method for class news_db
toHTML(x, ...)
```

**Arguments**

- |                  |                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>x</code>   | An object to display.                                                                                              |
| <code>...</code> | Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to <a href="#">HTMLheader</a> . |

**Value**

A character vector to display the object `x`. The "packageIQR" method is designed to display lists in the R help system.

**See Also**

[HTMLheader](#)

**Examples**

```
cat(toHTML(demo(package = "base")), sep = "\n")
```

---

**tools-deprecated**      *Deprecated Objects in Package tools*

---

**Description**

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

---

**toRd**      *Generic function to convert object to a fragment of Rd code.*

---

**Description**

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

**Usage**

```
toRd(obj, ...)
S3 method for class bibentry
toRd(obj, style = NULL, ...)
```

**Arguments**

- |       |                                                                       |
|-------|-----------------------------------------------------------------------|
| obj   | The object to be rendered.                                            |
| style | The style to be used in converting a <a href="#">bibentry</a> object. |
| ...   | Additional arguments used by methods.                                 |

**Details**

See [bibstyle](#) for a discussion of styles. The default `style = NULL` value gives the default style.

**Value**

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts `obj` to mode `character`, then escapes any Rd markup within it. The `bibentry` method converts an object of that class to markup appropriate for use in a bibliography.

## Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

## Usage

```
undoc(package, dir, lib.loc = NULL)
```

## Arguments

|         |                                                                                                                                                                                                                                                                    |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package.                                                                                                                                                                                                                    |
| dir     | a character string specifying the path to a package's root source directory. This must contain the subdirectory 'man' with R documentation sources (in Rd format), and at least one of the 'R' or 'data' subdirectories with R code or data objects, respectively. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                 |

## Details

This function is useful for package maintainers mostly. In principle, *all* user-level R objects should be documented.

The **base** package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments `.ArgsEnv` and `.GenericArgsEnv` in the **base** package that are used for various purposes: `undoc("base")` checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

## Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a `print` method for nicely displaying the information contained in such objects.

## See Also

## Examples

```
undoc("tools") # Undocumented objects in tools
```

---

`update_pkg_po`*Prepare Translations for a Package*

---

## Description

Prepare the ‘po’ directory of a package and compile and install the translations.

## Usage

```
update_pkg_po(pkgdir, pkg = NULL, version = NULL, copyright, bugs)
```

## Arguments

|                              |                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------|
| <code>pkgdir</code>          | The path to the package directory.                                                                       |
| <code>pkg</code>             | The package name: if <code>NULL</code> it is read from the package’s ‘DESCRIPTION’ file.                 |
| <code>version</code>         | The package version: if <code>NULL</code> it is read from the package’s ‘DESCRIPTION’ file.              |
| <code>copyright, bugs</code> | optional character strings for the ‘Copyright’ and ‘Report-Msgid-Bugs-To’ details in the template files. |

## Details

This performs a series of steps to prepare or update messages in the package.

- If the package sources do not already have a ‘po’ directory, one is created.
- `xgettext2pot` is called to create/update a file ‘`po/R-pkgname.pot`’ containing the translatable messages in the package.
- All existing files in directory `po` with names ‘`R-lang.po`’ are updated from ‘`R-pkgname.pot`’, `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under ‘`inst/po`’.
- In a UTF-8 locale, a ‘translation’ ‘`R-en@quot.po`’ is created with UTF-8 directional quotes, compiled and installed under ‘`inst/po`’.
- The remaining steps are done only if file ‘`po/pkgname.pot`’ already exists. The ‘`src/*.{c,cc,cpp,m,mm}`’ files in the package are examined to create a file ‘`po/pkgname.pot`’ containing the translatable messages in the C/C++ files. If there is a `src/windows` directory, files within it are also examined.
- All existing files in directory `po` with names ‘`lang.po`’ are updated from ‘`pkgname.pot`’, `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under ‘`inst/po`’.
- In a UTF-8 locale, a ‘translation’ ‘`en@quot.po`’ is created with UTF-8 directional quotes, compiled and installed under ‘`inst/po`’.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file ‘`po/pkgname.pot`’ in the package sources and run this function again.

`pkg = "base"` is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

## System requirements

This function requires the following tools from the GNU gettext-tools: `xgettext`, `msgmerge`, `msgfmt`, `msginit` and `msgconv`. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including OS X). Pre-compiled versions for Windows are available in <http://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip>.

It will probably not work correctly for en@quot translations except in a UTF-8 locale, so these are skipped elsewhere.

**vignetteDepends**

*Retrieve Dependency Information for a Vignette*

## Description

Given a vignette name, will create a `DependsList` object that reports information about the packages the vignette depends on.

## Usage

```
vignetteDepends(vignette, recursive = TRUE, reduce = TRUE,
 local = TRUE, lib.loc = NULL)
```

## Arguments

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| <code>vignette</code>  | The path to the vignette source                                        |
| <code>recursive</code> | Whether or not to include indirect dependencies                        |
| <code>reduce</code>    | Whether or not to collapse all sets of dependencies to a minimal value |
| <code>local</code>     | Whether or not to search only locally                                  |
| <code>lib.loc</code>   | What libraries to search in locally                                    |

## Details

If `recursive` is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If `recursive` is FALSE, only the dependencies directly named by the vignette will be used.

If `local` is TRUE, the system will only look at the user's local machine and not online to find dependencies.

If `reduce` is TRUE, the system will collapse the fields in the `DependsList` object such that a minimal set of dependencies are specified (for instance if there was 'foo, foo (>= 1.0.0), foo (>= 1.3.0', it would only return 'foo (>= 1.3.0)').

## Value

An object of class "DependsList".

**Author(s)**

Jeff Gentry
